Jameco sells the MC145151 PLL IC (On Semiconductor the Motorola spin-off still makes them) which, with a prescaler, can make a good, stable LO that is

channelized at 50 KHz increments for precise tuning. MC145151 is parallel-load for division, no extra IC needed to get the right division ratio as in some serial-input PLL or DDS chips.

Lots of inexpensive "all-band" radios off the shelf include the aviation band, those in addition to all the available VHF scanner receivers. Those all work better and more reliably than simple regens and super-regens in my observation.

Agreed - not that interesting to listen to, but the NAV channels are exactly what I'm interested in - (both VOR and LOC). The "experiment" I have in mind is a processor controlled scanner of sorts that tracks multiple VORs and performs as a backup to GPS. Hence the need for fast/agile tuning (either PLL or DDS). As you may have gathered - I'm not an "RF guy" by any stretch - but I'm attempting to learn (out of sheer necessity 8-).....

I'm not locked in to the MC1350 - it just happens to be what's used in the "ultra-cheap" kit I ordered. As it turns out, there's a company (Lansdale.com) that seems to be forming a business model around buying "obsolete" IP from Motorola et.al. and keeping the parts available. Interesting idea. As it happens, NTE has a drop-in replacement part for the MC1350 in their "NTE746" - available from Mouser. May be of interest to some on this group???

Well, even though (as I said) I'm not an RF-type I do
have quite a bit of test equipment laying around that I've
collected over the years. Among that stuff is an HP8654A
good to about 520 MHz that I've never used (and for the
life of me can't figure why I bought 8-).....

Thanks for the tip - I'm concerned about how long
such a thing might be available though. For now the
safest bet seems to be the National LMX series (or
the Analog Devices equivalents) - and adding a
processor for control is not a problem.

Thanks again for your input - it is appreciated!!!
Regards,
Bill

<snip>

Neither the range nor the accuracy of VORs is all that great on
the ground.

What do you intend to do with this doo-dad other than experiment if
I may ask?

HAH! I did **EXACTLY** that project back in 1996 or so.

Used the 145151 PLL that someone else reccomended.

The RX was the ... crud .. can't remember the part number ... That motorola 3300 part that was so popular. 3356 maybe?

Used a cheap 567 to track the FM part of the signal, and a simple envelope detector for the AM part. It was barely adequate for close-in stuff, and for long range stations, the noise performance was terrible.

The outputs of the two detectors went into a two-channel 8-bit ADC and were read by the CPU.

Used a 68HC000 for the CPU, and had a database of VOR stations burned into the ROM.

The cleverest piece of code was the CW decoder that was used to ID the stations.

It would tune around, listening to IDs and take a best-guess at where it was, then build a list of stations to scan, stopping on each one for a second to get a RMI fix. (There was a little crude LPF to help with the noise performance. Not that it did much good...)

I found some nice 4-line x 20 char LCD displays at a local junque shop, with ENORMOUS characters. 0.6" I Think .. Just HUGE for LCDs ... It would do a scrolling display of the form

SJC 025 nm @ 036
OAK 044 nm @ xxx

etc.

All in all it was a fun project -- with lots of cool learning experiences. In terms of practicality, the performance was never spectacular, RF noise from the CPU section would get into the IF (21.4 MHz)... it made a neat cockpit toy, but I would **NEVER** have considered it even a backup aid to navigation.

Just writing about this is making lots of little details come back to me. Feel free to e-mail and I'll bend your ear.

Firstly, the tower does NOT repeat voice comms over a VOR. The local Flight Service Station MIGHT, but in the days of crystal controlled navcoms, the amount of voice traffic on a VOR is next to nothing.

Secondly, the tower/FSS will never in HELL repeat something on a localizer frequency.

You are correct; the civilian aviation voice band is 118.000 to 136.975 MHz.

The 145151 is OK if you don't mind spurs every 25 kHz. from dc to daylight. The 145152 is a much better dual-modulo prescaler that gets rid of a lot of trash and garbage from single modulo prescaling that you probably don't want.

The absolute minimum operating voltage for the MC1350 is 12 volts. Not 11.9, 12. If this is a mobile application, then figure on a switching power supply to get you up to 15 volts or so.

Among that stuff is an HP8654A
> good to about 520 MHz that I've never used (and for the

Now, now, Jim. They do.

My residence is a mile and a half from BUR, roughly
eight miles from VNY here in the San Fernando Valley
area of Los Angeles.

Agreed, tower operators SELDOM repeat their transmissions
over the VOR but it is there in case it is needed. I've
heard them often enough.

VOR has an almost enormous bandwidth between 30 Hz and
the 9.96 KHz subcarrier phase reference...which was
INTENDED to carry voice as a conventience to the tower.

BUR, now the Bob Hope Airport, USED to carry the taped
weather broadcasts over their VOR but stopped several
years ago.

>Secondly, the tower/FSS will never in HELL repeat something on a localizer
>frequency.

Calm down. I may still vote for you next election,
but not if you act like Arnie... :-)

Hokay, I may have spoken hastily on the voice over
Localizer. Color me "probably wrong" there.

>You are correct; the civilian aviation voice band is 118.000 to 136.975 MHz.

Thank you. Sigh, I was only in the business of making
civil avionics and their test sets once. :-)

Sorry, I don't agree there. "Spurs" with an ordinary
PLL happen when the loop filter component values are
incorrect...and/or a higher frequency pole is used
(via an extra R and C in loop filter)to reduce higher
frequency components out of the PFD.

I've made a few PLLs with that MC145151 for homebrew
projects and not had any spurs from "DC to daylight"
or within the band of interest.

>The 145152 is a much better dual-modulo prescaler that gets rid of a
lot of
>trash and garbage from single modulo prescaling that you probably
don't
>want.

I've not tried the 145152 but, back a number of years
before On Semi split from Motorola Semi, a Motorola
factory person said the 152 is essentially the same as
the 151 except for the serial data interface. I can't
vouch for that but that's what I remember.

Single modulus prescaling (putting a simple divide by
8 or divide by 10 in series with the VCO and PLL IC
signal input) doesn't produce any more #$%^&!!! stuff
than going direct into the PLL IC signal input. That
is said PROVIDED the loop filter output line to the
VCO it is controlling is "clean" and doesn't pick up
other circuit signals. Such garbage pickup is the
common cause of "spurs" and is layout dependent, NOT
dependent on whether or not any prescaling is done.
There's some dependency on proper supply rail decoupling
for the phase-frequency detector and any active op-amps
used between the loop filter and VCO control input.

By the way, I've used the MC1350 down to 10 V supply
rails with no problem although I do agree with it
running optimally (for gain and noise figure) at 12 V
supply. There's a lot of internal constant current

sources on that IC and that causes the dependency on supply voltage. The same with the MC1349 which I'm working with now as both gain blocks and as mixers. I've worked with the MC1590 metal can original 34 years ago and the plastic package 1350 since 31 years ago. I like it as a little block of gain which has low distortion when running balanced input to balanced output...on up to 70 MHz with hardly any gain rolloff.

Note that the FM broadcast band is just below that band with lot of
strong transmitters, so any configuration with low side local
oscillator injection and the more or less standard 10.7 MHz first IF
is most likely going to give image frequency problems from FM
broadcast stations in the 86.6 .. 96.6 MHz range. To avoid this, a
good narrow tunable filter is required in front of the first mixer,
which can be a problem if good frequency agility is required.

One approach would be to use a much larger first IF or put the local
oscillator above the desired band (which also swaps the sidebands)
with image responses in the rest of the aviation band.

One idea would be to use a fixed downconverter e.g. with a 98 MHz
crystal frequency, mixing the VOR band down to 10-20 MHz, filter out
the strong mixing products from the FM broadcast band that is on
frequencies below 10 MHz and use a DDS with I/Q outputs to get I/Q
demodulation of the signal.

Class B linear, 3cx3000A7, Can be a final stage or used as
an exciter for 3cx1000000, hi hi, the B- doesn't not go to the grid but to
the centertap of the filimnet tranformer. well throught a cathode DC amp
meter...

On most modern amplifiers schematics they all seem to
use a b- lead which is basically the negative lead of the high voltage
lifted abouve ground by low ohm resister (10 ohms, 25w). Im sure this is
done for a reason. Im looking for input on way this matters,
thanks-Chuck

Sounds like a cool project! *MANY* years ago (circa 1984 or so?)
I had a plan to tear off the front panel of an RST radio I built and
replace it with a display, some controls and a zillion parallel bits to
replace all the thumbwheels switches - all driven by a Z80. I
eventually decided it would take way too long and didn't
accomplish much, besides just being a generally stupid idea 8-)..
So I sold the radio...

Now, twenty years later I'm playing with *this* project! All of
which proves that I now have way too much time on my hands and
I'm getting more stupid as I age 8-)......

Would like to hear more about your experiences. So, what would
you do differently if you were starting over?

I'm thinking that something like a cheapo DSP (or one of the new
dsPIC widgets) might be real handy. But first - I have to get past
the part where I have a reasonable RF front end! I really doubt that
the $40 Ramsey kit is going to do much but I bet I'll learn a few
things 8-).....

Thanks for that tip - it will be the first "improvement" to the cheapo
Ramsey receiver (which runs off 9 volts). The power supply is something
I *can* handle easily 8-)...

Well, give it a few weeks! Once the frustration level gets high
enough and I realize that I'm really a bit-banger and not a radio-head
I may be tempted to toss it (and anything else RF related) out the
window - in which case I'll pack it up and donate it to you 8-)...

In the meantime, any other suggested improvements or hints are
most appreciated (e.g. "up the IF from 10.7"?)...!

Thanks,
Bill (Who still thinks the universe *IS* digital - but infinite resolution
8-)

Thank you Paul - I'd like to look into this. Can you point me to some practical examples or reference materials to start with? Quite some time ago I ran across the articles from the flex-radio.com guys and was very interested in their approach. It's my understanding (and I mean a fairly fuzzy understanding) that direct conversion has many benefits but is limited to lower bands (unless you're the military with a big budget)??? What are the trade-offs in doing a downconversion followed by DDS-based conversion?

Chuck:

Placing the plate current meter in the B+ lead is risky unless the meter is well insulated from ground and mounted behind a glass or plastic panel so the operator can't accidently come in contact with high voltage.

Isolating the B- from chassis ground allows the plate current meter to be placed between the cathode and the power supply's negative terminal. The meter will then read plate current but won't have the HV B+ on it. A low value resistor is used between B- and the chassis to keep the voltage difference between chassis and B- small.

Is your triode amp configured for grounded grid operation? You can also place a second meter from cathode to chassis ground to read grid current.

If the B- from the power supply is grounded to the chassis and you have a single meter between cathode and ground, it will read cathode current which is the sum of plate and grid currents.

73,

Roger K6XQ

I think Roger has your answer. I thought you were seeing a B- power
supply - which is sometimes used in Class C finals for CW ops. What
you are dealing with is just a sampling point to sample current
without the high voltage insulation problem you would see with a B+
inserted current meter.

Message-ID: <bq3f31te7g61j7sp3aqld1kntuokneo0kl@4ax.com>
Source record: 19759

Trying to figure out what might be wrong with my My Wilderness Sierra. On transmit, the output power slowly goes from 0 to 1 watt after a miinute or 2. (Using a 40 watt band module, but does the same thing with other modules) - normal output should be about 2.5 watts. Maybe the final is going?, any tips before I actually have to start checking components, thanks Mike AB7RU

1577. 1030 MHZ and 1090 MHZ Filter Design

Newsgroup: rec.radio.amateur.homebrew

Source record: 19760

Hello!

I have no experience working with frequencies in the gigahertz range, but I am working on a project that broadcasts AM signals on 1030 MHZ and 1090 MHZ. It is the frequencies that airplane transponders communicate with ground stations on.

Does anyone have practical experience building a receiver for frequencies in this range? And what are some good suppliers for components at these frequencies?

I am looking for some example circuit diagrams and pcb layouts or something like that.

Thanks for any help.

>followed by DDS-based conversion?

My suggestion of using a DDS for direct conversion in the 10-20 MHz
range is based on the assumption that DDS chips running with 50-60 MHz
clock frequency should be available at a quite a reasonable price,
compared to similar chips running at 400 - 500 MHz, which would be
required for direct synthesis in the VHF band.

However, translating the whole band down to HF requires a strong down
converter, especially due to the nearby strong signal broadcast band.
Some flimsy NE602 type converter will not survive very well in such
environment, but a high current preamplifier followed by a diode ring
mixer might be a better converter.

1579. " BIG BUCKS" WITH ONLY $6.00 INVESTMENT "NO BULL"!!!!

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-03-16 18:43:53 UTC
From: bscruggins2000@yahoo.com
Message-ID: <1110998633.093816.65610@l41g2000cwc.googlegroups.com>
Source record: 19762

HOW TO TURN $6 INTO $6,000!!!!!! READING THIS COULD CHANGE YOUR LIFE!

I found this on a bulletin board and decided to try it. A little while back, I was browsing through newsgroups, just like you are now, and came across an article similar to this that said you could make thousands of dollars within weeks with only an initial investment of $6.00! So I thought, Yeah right, this must be a scam,but like most of us, I was curious, so I kept reading. Anyway, it said that you send $1.00 to each of the 6 names and address stated in the article. You then place your own name and address in the bottom of the list at #6, and post the article in at least 200 newsgroups. (There are thousands) No catch, that was it. So after thinking it over, and talking to a few people first, I thought about trying it. I figured: what have I got to lose except 6 stamps and $6.00, right? Then I invested the measly $6.00. Well GUESS WHAT!!... within 7 days, I started getting money in the mail! I was shocked! I figured it would end soon, but the money just kept coming in. In my first week, I made about $25.00. By the end of the second week I had made a total of over $1,000.00! In the third week I had over $10,000.00 and it`s still growing. This is now my fourth week and I have made a total of just over $42,000.00 and it`s still coming in rapidly. It`s certainly worth $6.00, and 6 stamps, I have spent more than that on the lottery!! Let me tell you how this works and most importantly, why it works....Also, make sure you print a copy of this article NOW, so you can get the information off of it as you need it. I promise you that if you follow the directions exactly, that you will start making more money than you thought possible by doing something so easy!
Suggestion: Read this entire message carefully! (Print it out or download it.) Follow the simple directions and watch the money come in! It`s easy. It`s legal. And, your investment is only $6.00 (Plus postage)

IMPORTANT: This is not a scam; it is not indecent; it is not illegal; and it is virtually no risk - it really works!!!! If all of the following instructions are followed exactly, you will receive extraordinary dividends.

PLEASE NOTE: Please follow these directions PERCISELY, and $50,000 or more can be yours in 20 to 60 days. This program remains successful because of the honesty and integrity of the participants. Please continue its success by carefully adhering to the instructions. You will now become part of the Mail Order business. In this business your product is not solid and tangible, it`s a service. You are in the business of developing Mailing Lists. Many large corporations are happy to pay big bucks for quality lists. However, the money made from the

mailing lists is secondary to the income which is made from people like you and me asking to be included in that list. Here are the 4 easy steps to success:

STEP 1: Get 6 separate pieces of paper and write the following on each piece of paper; PLEASE PUT ME ON YOUR MAILING LIST. Now get 6 US $1.00 bills and place ONE inside EACH of the 6 pieces of paper so the bill will not be seen through the envelope (to prevent thievery). Next, place one paper in each of the 6 envelopes and seal them. You should now have 6 sealed envelopes, each with a piece of paper stating the above phrase, your name and address, and a $1.00 bill. What you are doing is creating a service. THIS IS ABSOLUTELY LEGAL! You are requesting a legitimate service and you are paying for it! Like most of us I was a little skeptical and a little worried about the legal aspects of it all. So I checked it out with the U.S. Post Office (1-800-725-2161) and they confirmed that it is indeed legal! Mail the 6 envelopes to the following addresses:

Mailing Addresses

1. P. FREY, 4577 W. PONDS CIR, LITTLETON, CO 80123
2. E. DE LEON, 14014 Rosecrest, Houston,TX 77045
3. A. Lopez, 810 Ave.J, South Houston TX 77587
4. L. Pacheco, 812 Ave.J, South Houston, TX 77587
5. K. Bat, 9335 Alcona Street, Lanham, MD 20706
6. B. Scruggins, P.O. Box 845 Port Barre, LA 70577

STEP 2: Now take the #1 name off the list that you see above, move the other names up (6 becomes 5, 5 becomes 4, etc...) and add YOUR Name as number 6 on the list.

STEP 3: Change anything you need to, but try to keep this article as close to original as possible. Now, post your amended article to at least 200 newsgroups. (I think there are close to 24,000 groups) All you need is 200, but remember, the more you post, the more money you make! This is perfectly legal! If you have any doubts, refer to Title 18 Sec. 1302 & 1341 of the Postal lottery laws.
Keep a copy of these steps for yourself and, whenever you need money, you can use it again, and again.

PLEASE REMEMBER that this program remains successful because of the honesty and integrity of the participants and by their carefully adhering to the directions. Look at it this way. If you are of integrity, the program will continue and the money that so many others have received will come your way.

NOTE: You may want to retain every name and address sent to you, either on a computer or hard copy and keep the notes people send you. This VERIFIES that you are truly providing a service. (Also, it might be a good idea to wrap the $1 bill in dark paper to reduce the risk of mail theft.)
So, as each post is downloaded and the directions carefully followed,

six members will be reimbursed for their participation as a List Developer with one dollar each. Your name will move up the list geometrically so that when your name reaches the #1 position you will be receiving thousands of dollars in CASH!!! What an opportunity for only $6.00 ($1.00 for each of the first six people listed above) Send it now, add your own name to the list and you`re in business!
---DIRECTIONS ----- FOR HOW TO POST TO NEWSGROUPS---------- Step 1) You do not need to re-type this entire letter to do your own posting. Simply put your cursor at the beginning of this letter and drag your cursor to the bottom of this document, and select `copy` from the edit menu. This will copy the entire letter into the computer`s memory.

Step 2) Open a blank `notepad` file and place your cursor at the top of the blank page. From the `edit` menu select `paste`. This will paste a copy of the letter into notepad so that you can add your name to the list.
Step 3) Save your new notepad file as a .txt file. If you want to do your postings in different settings, you`ll always have this file to go back to.

Step 4) Use Netscape or Internet explorer and try searching for various newsgroups (on-line forums, message boards, chat sites, discussions.) Just example you log on any search engine like, yahoo.com,google.com, altavista.com,excite.com then you search with this subject millionaire message board? or money making message
board? or employment message board? or money making discussions? or money making forum? or business message board? etc. You will find thousand & thousand message board. Click one by one then you will find the option post a new message.
Step 5) Visit these message boards and post this article as a new message by highlighting the text of this letter and selecting paste from the edit menu. Fill in the Subject, this will be the header that everyone sees as they scroll through the list of postings in a particular group, click the post message button. You`re done with your first one! Congratulations...THAT`S IT! All you have to do is jump to different newsgroups and post away, after you get the hang of it, it will take about 30 seconds for each newsgroup!

REMEMBER, THE MORE NEWSGROUPS YOU POST IN, THE MORE MONEY YOU WILL MAKE!! BUT YOU HAVE TO POST A MINIMUM OF 200
That`s it! You will begin receiving money from around the world within days! You may eventually want to rent a P.O.Box due to the large amount of mail you will receive. If you wish to stay anonymous, you can invent a name to use, as long as the postman will deliver it.
JUST MAKE SURE ALL THE ADDRESSES ARE CORRECT.

Now the WHY part: Out of 200 postings, say I receive only 5 replies (a very low example). So then I made $5.00 with my name at #6 on the letter. Now, each of the 5 persons who just sent me $1.00 make the MINIMUM 200 postings, each with my name at #5 and only 5 persons respond to each of the original 5, that is another $25.00 for me, now

those 25 each make 200 MINIMUM posts with my name at #4 and only 5 replies each, I will bring in an additional $125.00! Now, those 125 persons turn around and post the MINIMUM 200 with my name at #3 and only receive 5 replies each, I will make an additional $626.00! OK, now here is the fun part, each of those 625 persons post a MINIMUM 200 letters with my name at #2 and they each only receive 5 replies, that just made me $3,125.00!!! Those 3,125 persons will all deliver this message to 200 newsgroups with my name at #1 and if still 5 persons per 200 newsgroups react I will receive $15,625,00! With an original investment of only $6.00! AMAZING! When your name is no longer on the list, you just take the latest posting in the newsgroups, and send out another $6.00 to names on the list, putting your name at number 6 again. And start posting again. The thing to remember is: do you realize that thousands of people all over the world are joining the internet and reading these articles everyday?, JUST LIKE YOU are now!! So, can you afford $6.00 and see if it really works?? I think so... People have said, "What if the plan is played out and no one sends you the money? So what! What are the chances of that happening when there are tons of new honest users and new honest people who are joining the internet and newsgroups everyday and are willing to give it a try? Estimates are at 20,000 to 50,000 new users, every day, with thousands of those joining the actual internet.

Remember: Play FAIRLY and HONESTLY and this will really work.

Slight correction: The 1030/1090 MHz frequencies are
an aid to FAA local search radar to help discriminate
targets and to IDENTIFY targets shown on their radar
display screens. That isn't "communication" per se.

The ground station interrogator antenna physically
rides on top of the search radar dish. It has a VERY
narrow horizontal antenna pattern. The interrogation
signal is a repetitive PULSE pair...fairly high power,
usually better than a hundred Watts peak. An aircraft
transponder receives all signals on that frequency and
uses one of several types of "coincidence detectors"
to separate received pulse pairs from single pulse
signals or "fruit" (avionics term, not mine). At a
fixed time delay, the transponder sends out its own
PULSE pair...plus a PULSE ID code (in octal number
arrangement of two 0-7 numbers or four 0-7 numbers).
The ground station receiver processor strips out the
valid aircraft responses and ID from "fruit" and
sends that to the search radar display unit.

Bandwidth is roughly 30 MHz for those two carrier
frequencies so radar receiver techniques apply.

>Does anyone have practical experience building a receiver for
>frequencies in this range? And what are some good suppliers for
>components at these frequencies?

I do. It's the bottom end of L-Band (1 to 2 GHz) and
in a "nasty" transition range of lumped tuned circuits
into distributed tuned circuits. Cellular and cordless
phones ("old" style in the pulse range, not the newer
2.4 GHz cordless variety) fall into that range.

Ain't NO "good suppliers for components" of front ends
since all of those are designed at the factory or sub-
contracted. Front end tuning is probably simplest using
capacitively-loaded coaxial cavities, whether solid-state
or vacuum-state active devices are used. Stripline can
be used there although those get relatively large at
1 GHz. NOS pencil triodes can be used to achieve high

enough peak RF pulses but I've no experience in AM for
those. Radiosondes/rawinsondes used pencil triodes
crimped into sheet metal cavities at 1.6 GHz. A small
boat radar (short range) used to be sold by a company
called Bonzer three decades ago, used those pencil
triodes with an array of helix antennas in what looks
like a large "TV" style pancake radome. I've seen
lots of similar ones around the marinas here.

IF strips are just radar-style, can be 30 to 60 MHz
center, a relative piece of cake to build, plenty of
textbook data on such from the last 6 decades.

>I am looking for some example circuit diagrams and pcb layouts or
>something like that.

Uh-uh. Good luck when the federal marshalls show up
at your door along with an FCC field engineer, maybe
a pissed FAA official.

INTERFERING, however slight, with an ATC radar
interrogator system, is NOT A GOOD THING. DO NOT
DO THAT!

You just want some "examples?" Buy an aircraft
transponder. Reverse engineer it. Maybe $2K for a
used unit? DO NOT USE IT FOR "COMMUNICATIONS."

If you want to do "piracy" on UHF, there's plenty of
RF space in unused TV channels. FCC has the listings
of old and new (DTV) channel occupancy by city. FCC
also regulates all U.S. civil radio and they do NOT
take kindly to anyone interfering with FAA ATC ops
and those very reserved bandspaces.

Direct conversion (DC) won't be effective on this
application for reasons of the civil aviation band
being AM with no pilot carrier or other reference.
Look into the allowed carrier tolerances and you will
see that, unless you can definitely LOCK onto the
incoming carrier, there will be a great change in the
modulation information, both in frequency and phase.

That is particularly true with VOR. The ground
station antenna pattern is (now) electronically
rotated at 30 Hz and the reference phase
(representing magnetic north) is FM on the 9 KHz
subcarrier. Without a proper phase relationship,
the bearing signal will be very inaccurate.

The VOR system was designed/innovated/invented over
a half century ago and was elegant in simplicity
for simple circuitry in vacuum-state hardware. The
first lightweight VOR receivers in light aircraft
used a (very old technology) small goniometer as
part of the OBS or Omni-Bearing Selector and their
accuracies were dependent on how well the goniometer
was designed and manufactured. [a goniometer is a
coaxial spherical toroid pair, best illustrated in
"Lowfer" or low frequency - below AM BC band -

small handbooks and some websites] More modern versions use an electronic equivalent of phase shifting at 30 Hz as part of the OBS subsystem.

A VOR antenna pattern rotation results in about 30% AM at a 30 Hz rate. The magnetic north phase reference is 30 Hz FM on the 9960 KHz subcarrier. The FM demodulation will have a limiter stage ahead of it to effectively wash-out the 30% AM of the ground station antenna pattern rotation. In between the 30 Hz of the ground antenna pattern rotation and about 8 KHz or so of the lower limit of the 30 Hz FM on subcarrier phase reference is "empty space" that was reserved for optional AM from a local Flight Service Station (FSS) or tower transmission. In short, the elegance of the concept was ideally suited to vacuum tube circuitry, that being an almost ultimate simplicity at the time...and very light weight necessary for aircraft.

The "big bucks" of military electronics doesn't go wild over fancy schmancy arrangements of the very "in" modern complications. Those "big bucks" are spent in making the hardware work over the totally gargantuan range of temperatures and physical shock and vibration that would tear apart consumer electronics style structures. The civil avionics market is not, nor has it ever been, large compared to consumer electronics products, hence their costs appear high.

There IS room for experimentation in ways to demodulate the VOR information, don't get me wrong. What you must do is to FIRST concentrate on the characteristics of how the bearing information is conveyed...along with all the problems introduced by multi-path distortion from ground objects around you. Those problems aren't there in the aircraft flying a few thousand feet above all those reflecting objects. [an exception is a VOR in a helicopter and its own rotors...but that is another story in itself]

Just because the FM BC band upper end is at 108 MHz doesn't automatically mean there WILL be RFI to the receiver. That's a matter of checking a local area to find where all those fixed FM BC carriers are and how strong they are. Aircraft VOR receivers have been overflying all sorts of FM BC stations for a half century all over the world and there aren't any stories (except invented horror tales) of terrible interference from FM. Simpler civilian receivers,

not the "big bucks" of military aircraft.

Just offhand, I'd say a simple, even tube-based, bearing information receiver can be hacked together to get +/-5 degrees accuracy using the simplest circuitry with minimum test equipment to check it out. Anything better is just finesse, bottoming out at the basic accuracy of whatever VOR ground station is used. That would be +/-1 degree but worse from any ground reception multi-path effects.

VOR (Very high frequency Omnidirectional radio Range) was designed only for aircraft obtaining bearing information to a fixed ground station. That's a limited application although extremely important to pilots. A half century ago it was a quantum leap above older raw-DF-style radionavigation. GPS it ain't, nor never was...

They are called transponders.

You can use a generic satellite receiver to pick it up, they tune from about
950 MHz to 1450 MHz, on the cable from the LNA
The old c-band satellite dish stuff, just take off the LNA and put a good
antenna on the end of the cable, you can make one out of a 1 gallon paint
can. You can buy a low end new satellite receiver for $200, or get a used
off ebay.

The band is easy to design in, for receivers.

I'd probably jack the IF up to 45 MHz. (use TV parts; this is the TV IF frequency) or 70 MHz. (satellite IF frequency), and then downconvert to either 21.4 or 10.7...there are cheap crystal filters at both frequencies.

Well, that was certainly a very informative and well thought
out response! But GEEZ, Len, you're starting to take all the
fun out of this by insisting on injecting reality!!!....8-)

Here I was - with soldering iron warmed up and pile of odd
looking components (SA-614, MC1350, NE567, inductors,
IF transformers and all kinds of other "stuff" that's unfamiliar)
and now my hopes are dashed.....

I even checked Mouser, Digikey et. al. - and they're fresh out
of goniometers - so there goes *that* approach...8-(

But seriously - let's look at the potential utility of a fairly "mindless"
NAV receiver as it might apply to the non-instrumented-rated,
day-VFR "Sport" or "Recreational" pilot. First off, these guys
believe that GPS coupled to a simple moving map display represents
not only the holy grail - but they'd be willing (foolishly) to bet their
lives on this sole-source nav capability (never mind simple "dead
reckoning" or other elementary - e.g. "follow roads" forms of
navigation). If the batteries run out on the GPS - or the guys at
Cheyenne Mountain pull the big red lever marked "scramble GPS"
for whatever reason - they're in big trouble. Standard VOR-based
equipment would give them a way out - but they don't have it ('cause
it costs too much) and they wouldn't know how to effectively use it
anyway ('cause they aren't instrument rated). Some form of relatively
simple (albeit far from accurate) NAV capability would at least give
them a last chance to drag out the sectional and try to determine roughly
where they are - hopefully close enough to find a place to put down.

My ridiculous little experimental project is to try and come up with a "poor man's" (and perhaps "stupid man's 8-) nav capability based on VORs which is inexpensive and SIMPLE. There's no OBS nor any other "normal" features (e.g. ability to drive a CDI) - but it kicks out enough info relative to a few nearby VORs so that you can at least determine what planet you're on 8-).... and provide a few hints as to *where* you are on that planet...

GPS replacement? Absolutely not. TSO'd NAV receiver replacement? Nope - not that either. Inexpensive (enough so that you might actually install one) and simple (enough so that you could derive some useful info with little training) - that would be the goal.

In the meantime, it's really a personal educational and entertainment toy to play with, and nothing more ("amateur", "homebrew", etc. - so it's relevent here, right?).....8-)

I appreciate your thoughts and comments, Len! You obviously have a wealth of experience to draw upon and I thank you for sharing it. Despite more than 25 years in product development, most of this is new territory for me (and I'm enjoying the learning experience!). I've never done an RF design - well - at least not "deliberately"!!!

Regards,
Bill

If that happened, and that's a pretty big if given the US government
is forcing GPS as the defacto navigation standard for just about
everything, the accuracy would be reduced to such that it would be
impossible to make a precision approach.

The remaining accuracy would be more than enough to find an airport,
especially since Sport and Recreational are limited to day VFR.

Standard VOR-based
> equipment would give them a way out - but they don't have it ('cause

Sporty's sells the SP-200 NAV/COM handheld for $299.00 with a $14.95
rebate if you use your AOPA credit card. It has VOR and LOC with a
digital CDI display and 2,280 channel COM. You still would have to
know what 235 FROM means.

IMHO anyone not flying a big turbine with multiple redundent everything
that doesn't have a handheld just in case is foolish.

Decoding the bearing can be done with a PLL running as a 360X frequency
multiplier on one 30 Hz signal and using the other to gate a counter
which is feed the multiplied signal.

I built such a beast in '75 as a senior project with a NIXIE tube
display. Available compenents have improved a lot since '75.

If I were to do something like this today, I think I would look for
someone's receiver module and use a microcontroller to control the
receiver and do most (maybe all with DSP) the decoding, feeding it all
to a PDA with a database of VOR frequencies and locations and use the PDA
to generate a map display.

It would be a fun project.

I am going to use the same car antenna for AM/FM and 2M. This means I need a diplexer that transitions somewhere between 108 and 144 MHz. I haven't seen something like this offered commercially. Has anyone seen a product like this, or failing that, a design I could duplicate? The antenna will be a 1/4 wave on 2M, and would also be used as a (not quite ideal) AM/FM antenna.

Unless I require simulation of some sort, nothing is faster than drawing by hand. When talking to clients, it much faster for me to do a quick back-of-envelope sketch than it is to fire up my comp. My drafting skills are of quite a high standard and there will be times where I won't enter the design into my computer at all.

For final designs(paid ones) I usually use Protel. Its expensive but its widely accepted and its a complete package, and I pass the costs onto my customers anyway.

For just recording circuits for later reference, I really like DraftChoice for Windows (shareware). It is a general purpose drawing program, but is very intuitive and fast to get something down. It allows you to build libraries of symbols and I have a blank schematic drawing all set up with the library included. Then, after you get things connected up, you can select rectangular areas and stretch all the lines passing through that boundary (but the symbols do not stretch) allowing you to straighten the drawing up or make room for changes. Its files are very compact. It also supports many layers and colors and you can turn each layer on or off or protect it from changes as needed. I often put a parts list or theory of operation or other notes on a hidden layer.

Some of its weaknesses are that it does not export to many graphic formats (I usually just hit the print screen key and past to some other graphic program to email a gif) and the symbols do not have text fields, so you have to put the values on as a separate operation.

If you are running an I/Q DDS feeding I and Q demodulators (mixers) and low-pass filter the quadrature demodulator, producing a DC voltage proportional to the phase error. This could be used through an ADC to control the phase modulator input (or the phase accumulator addend) of the DDS to track the signal. However, DDS chips with only serial input might be too slow to track the signal. The I demodulator output would provide the amplitude modulated information.

Hi,
I have been given an ic745 internal power supply.
I was wondering if i can use it as a stand alone external one.
it has the standard 6 way power connector with 2x positive and 2x negative outputs.
but it also has 2 other wires to the plug. (i presume these are a switch on sensor?)
If i apply mains to the unit there is no output so I will need some way of imitating the power on switch on the rig it is from.
Any help gratefully accepted. Bob.

Phil - I'm only about 98% sure but I think all the charging
circuits are in the radio and battery. I converted my VX-2R's
power cable by installing RCA connectors half way between
the wall wart and plug. I then bought a 4xAA dry cell case
and put an RCA connector on it. Now I can run 3w and
recharge the Li-Ion pack, all from a set of energizers.

BTW you might want to join our group - almost 1,200 users
all with VX-2's....

1605. Low Power AM Broadcasting

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-03-17 16:20:54 UTC
From: WCRV@webtv.net
Message-ID: <10700-4239AE66-153@storefull-3317.bay.webtv.net>
Source record: 19790

The Low-Power AM station hobby has become more popular over the past 2 years.
In the U.S, it is legal to broadcast over the AM band 540kHz-1700kHz using a 3
meter antenna and a 100mW transmitter.
Until recently, building a small AM radio station was very complicated and very expensive, until now.
Using a SSTRAN AMT-3000 transmitter, which comes as a kit for under $100.00US, or a built version which comes assembled and tested for under $200.00 US, and a 3 meter, coil loaded and tunable antenna for around $225.00 US, anyone can get on the air right now!
I get questions about range: the system I am describing has had reports from 1/2 mile to over 4 miles! Range totally depends on these factors: location, scope of the land, conductivity, choice of frequency/adjacencies, and use of this antenna.
If the transmitter and antenna are installed correctly in a proper area, several miles are possible. Many people are interested in a good, solid local signal and this system does it for a fraction of the amount of money you will spend for a comparable system.
If you are interested in low power AM Broadcasting, I invite you to visit this site:
http://antenna18431.tripod.com/antenna.htm
In this site you will find information on the 3 meter antenna, pictures of it, information and pictures of the transmitter and a link to email questions, comments and inquiries to.
If you would like to be on the air, this is an excellent choice to do it well, and at a very affordable price!

Ken,

Thanks for some very good info. I was hoping that was the case.
This opens up the possiblity of making a 12 volt mobile charger
and using the solar panel for free re-charges too.

I'll pass on the Yahoo groups. Newsgroups are wide open and
full of great folks like yourself with lots of good info.

73,

phil

1610. Re: using icom internal power supply as an external ps?

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-03-17 20:55:06 UTC
From: Steve <nospam@bit.bucket>
Message-ID: <d1cr41$r7g$1@grandcanyon.binc.net>
Source record: 19793

Bob,

If you hunt about the Internet, you may even be able to find a pdf service manual for this rig.

I agree you can probably use it for a general power supply. There's a caveat of two, however. 50% duty cycle, so says the service manual. Also, there may be an issue of minimum loading for any switching power supply; you may want to add say a resistor or 12 V light bulb for say a 1 Amp load, though there's nothing in the manual that mentions min load. A quick look of the rig specs didn't reveal a current draw of the IC745 on receive.

Bob G0KYF wrote:

> Hi,
> I have been given an ic745 internal power supply.
> I was wondering if i can use it as a stand alone external one.

According to the hard copy service manual I have for my IC745,

Input Voltage: 110/220 AC 50/60 Hz +/- 10%
Input Capacity: 550VA @ 20A
Max Load 20A: 10 mins ON/10 mins off

Fuse 10 A, 110 and 5 A for 220.

> it has the standard 6 way power connector with 2x positive and 2x negative
> outputs.
> but it also has 2 other wires to the plug. (i presume these are a switch on
> sensor?)

Yes, the schematic shows this going to a simple switch. Short pins 3 & 6 to turn on.

Pin out
1 4 13.8 Volts
2 5 GND
3 6 "AC 1 & AC 2"

> If i apply mains to the unit there is no output so I will need some way of
> imitating the power on switch on the rig it is from.
> Any help gratefully accepted. Bob.

The manual also mentions automatic 25 A current limit, turn off to reset.

Good Luck, Steve

Parts are on the way...

First IF = 45 MHz
Second IF = 10.7 MHz

Any point in going further to 455 KHz for a third IF or just stick
with the 10.7 -> (MC1350 plus IF transformer) scheme?

In amps with multiple tubes in parallel it is a good idea to use
matched tubes if possible (you can get matched 811A's). Some amps
have bias adjustments for each tube so you can match idle current
on the tubes (don't think yours does though). IIRC the amertron
4 tube 811A amp DOES have a small neutralazition cap, the 3 tube
one does not. The manual should tell you how to adjust the
neutralization, however in most cases it only matters on 10 meters.

The antenna mentioned is most likely illegal. If you have a 3 meter antenna, it must be connected to the transmitter without the benefit of a transmission line and ground lead. Don't take my word for it, ask the FCC. I did. Here is my question and their reply (note the 3 meters includes antenna, connecting lead (transmission line) and ground lead):

"Question:

Concerning the 3 meters maximum length for antenna, transmission, and ground, would a capacitance hat at the top of a vertical radiator be included in the 3 meter limit?

For clarification: Suppose I put a 3 meter vertical monopole on top of an existing structure which has a metal roof. The transmitter would be located at the base of the monopole, so it would require no transmission

line. Would I be allowed to install a 3 meter diameter (or more) top hat? The top hat would be shaped like a spoked wheel and would serve the purpose of increasing the current in the monopole through capacitive coupling to the metal roof ground.

Answer:

The intent of Section 15.219 is for a maximum 3 meter wire antenna.

The total length of the antenna plus ground lead plus connecting lead must not exceed 3 meters. The rule doesn't permit a 3 meter diameter "top hat" but should be applied to the combined length of each radial. If the combined length of each radial added to the length of the antenna vertical structure added to the length of the ground wire exceeds 3 meters, it would not be permitted."

Actually that is the first thing I suggested but the owner doesn't want to
go that route unless he absolutely has to. I have heavy Teflon coated wire
that would work (the actual wire size is #16 I believe). We may have to go
that route if no cap is found. I believe the plate voltage on the 6136 tubes
is about 850 - 900 volts DC so probably 2000 volts AC (RF).
Thanks for your input.

I have done this. (OK, I think the supply came out of a IC-271H) If I recall properly the load was a TS-130 and it worked fine.

Unfortunately that was 20 years ago and I don't remember the wiring.

I would go directly from 45MHz to 455kHz.............this is typical in HF receivers. An NE602 mixer can be used for the 2nd mixer and a 44.545MHz crystal used with the on-board oscillator allows you to derive your 2nd I.F. Alternatively, you can use a TDA1572 as the 2nd mixer/I.F./ demodulator. This is also a good system and it will give you fairly good strong signal handling capability.

Hi All,

Does anyone know if a Darlington transistor (IC of two transistors in Darlington congifuration) can be biased at class C for use in an output stage of a VHF transmitter? Darlingtons seem to have pretty high gain, so I supposed they could reduce the number of stages required to amplify an RF signal? Thanks in advance.

You have to look at the fT parameter (which specifies the frequency at
which _current_ gain drops to unity), since a typical power darlington
is a very slow device.

Has anyone built an AM/FM tuner using PLL synthesizer and micro controller chips? There is some documentation using i2c bus, however I cannot find any microprocessor i2c chips that mate to the TSA6057 synthesizer. Thanks in advance.

1625. variable speed pot ground?

Newsgroup: rec.radio.amateur.homebrew

Good Morning,

I am putting together a winkey keyer kit (I know it is not true homebrew, but I am just a lowly English teacher). Anyways, I have a variable pot with three poles and need to know which one is ground. How can I find that out with a multimeter?

Thanks and 73

Do you mean you want to know which tag is attached to the wiper? If that is what you mean, just measure the resistance between any pair of terminals, the pair for which the resistance does not change regardless of position of the pot, neither pin will be the pin you want.

Its usually the centre one.

You can implement I2C on any MCU, using software. Many have hardware I2C
include the MegaAVRs and the Philips LPC2000 ARM family.

Ok, it is the center one. I guess i needed to think outside the box as the schematic has it showing, from how I interpreted it, one of the ends. Great! Thanks for the quick response. Now I can install and play. Maybe you'll here me on 40.

Is what you're building the same thing as on
http://k1el.tripod.com/winkey.pdf ?

If so, it really doesn't matter! You use the center terminal (the wiper) and one end, it doesn't matter which end. The consequences of getting it "wrong" are that the control will work "backwards" - you'll turn the pot counter-clockwise to speed up your Morse, instead of clockwise. If that happens, you can fix it by using the other end terminal. You won't damage anything by getting it wrong.

==========

In general, for any other future construction projects you may get involved in... it is VERY unusual for the wiper of a pot to be connected to ground. It does happen - it would be acceptable to do so in this Winkey circuit and I have seen others - but it is VERY rare. In some circuits, grounding the wiper when you shouldn't could result in damage to the pot (and possibly other parts). And almost always, the circuit won't work, or at least won't work properly.

Getting the two ends mixed up is far less dangerous. The worst consequence is the same as it is with the Winkey: the control will work backwards and you can fix it by swapping the ends.

I'd hesitated to post since I wasn't sure of the sort of selectivity needed.

But yes, if the selectivity is available at 455KHz, there's no need to
have something in between that and 45MHz (or for that matter, if the
right selectivity can be had higher, gain is the only reason for going down
to 455KHz.

Old cellphones, the big and bulky kind, have IFs in the above 30MHz range
(the exact frequency has varied, but I think the majority of those that I've
stripped have had 45MHz IFs. And they tend to drop down to 455KHz after
that, meaning a scrap cellphone (the older the better because they
are cheaper and the parts are bigger) will generally provide a "roofing
filter" and the crystal to get down to 455KHz from there, and even the
455KHz filter if it doesn't have to be narrow.

No terminal of a pot is grounded inside the pot. It is just a chunk
of resistance with a terminal on each end sliding contact in the
middle.

I think you need to connect the bottom terminal (when you are looking
at the end of the shaft and the terminals are to the left) to ground
and the middle one (the wiper) to the speed control input (S).

Standard GX-3000 VHF APRS Radios. [with DTMF]
I have a quantity of Commercial Standard GX-3000 VHF Mobile Radios
(136-150Mhz) 25-30 Watts O/P These radios will work excellent as an APRS
Mobile OR Base Radio Station. Units are much cheaper to use for dedicated
APRS use rather than spending Large Dollars for a VHF Amateur XCVR and
dedicate it to APRS use. Programmed & Tested Operational on 144.390 Mhz.
You will have to make up the Interface Cable. These radios are capable of
64 Channels, Carrier Squelch Only and I can program them for other 2 Meter
Frequencies for a charge. Please ask should you have any questions.
Cost: $ 45 USD Plus Shipping

Ditto all the comments already made (except that you probably want to ground one of the ends rather than the wiper), plus: A potentiometer is nothing more than a strip of resistive material with terminals at each end and a movable contact attached to the knob somewhere in the middle. The movable contact is called the "wiper" because, well, it wipes.

If you ignore audio taper pots the resistance between any two points along the length of the strip is proportional to the distance between the points. So if you have a 2" long strip in a 20k-ohm pot, and you place the wiper 1/2 inch away from one end, you'll see 5k-ohms between the wiper and that end (and 15k-ohms between the wiper and the other end).

Potentiometers almost always come with three leads, and the leads are almost always arranged so that the middle lead is the wiper -- the only exception I know is with some precision multi-turn pots, but you can ignore those. The drawing below shows the correspondence between a schematic drawing of a pot (euro-style, kinda -- just take the box to be the usual squiggly line) and a drawing of a panel-mount pot.

Source record: 19819

A major problem with the speed is that a common three-terminal Darlington doesn't have any pulldown resistor or current sink to the Q1e-Q2b connection. That leaves no good way to remove charge from Q2b quickly when you want Q2 to turn off. If you can find one with an internal Q2b-Q2e resistor of pretty low value, or better yet have access to that junction so you can long-tail it down to a negative supply or even to ground, you'll have a much faster switching device. I still suspect you'll have trouble getting one to go fast enough for efficient class C operation at VHF.

perhaps not so much for RF, but I wonder why you don't see NPN/PNP
combination for darlington transistors - with Vbe = 0.55-0.6V

I thought darlington transistors were just two transistors connected
that way inside the same case, ie not particularly different from
connecting two discrete transistors in the same configuration.

Hence, one could play with darlington transistors, but just
use two distinct transistors, so you have that junction.

Of course, there are other reaosn for having an amplifier chain, besides
overall gain. Those intermediate stages often help to filter the signal.

>>
>> Bill

As a suggestion (too late if parts are incoming), a
single conversion to a 21.4 MHz IF is quite suitable.
Using a monolithic quartz crystal filter (available
from DigiKey for about $15 a pair of two) between
the mixer and first IF could eliminate ALL tuned
circuits in the IF following the 1st IF amplifier.
Those are available in 12.5 KHz bandwidth which will
be fine for a VOR signal. [DigiKey has a link to
download specs for the ECS-made monolithics]

This is now common in mobile radios, both new and
retrofit of older ones.

If a single-conversion scheme with 21.4 MHz is done,
the LO can be 86.6 to 96.6 MHz with an image at
65.2 to 75.2 MHz. That is a low enough frequency
to allow a simple L-C "top coupled resonator" fixed

bandpass filter for the front end at 108 to 118 MHz (8.9 % bandwidth).

Doing double conversion with a first IF of 45 MHz is, by itself, no problem. However the 2nd IF image is a bit too close to the nominal bandwidth of any 45 MHz 1st IF tuning (it's only 0.91 MHz away). With the second's image (on either side depending on 2nd LO above or below 45 MHz), there's still a chance to pick up part of the FM BC band locally. To avoid that, the 2nd LO should be on the high side of 45. Second IF image would then fall into the low end of the 118 to 137 MHz comm band (also AM) and those transmitters are much lower powered ones than BC stations.

With a 10.7 MHz 2nd IF, its image would be 21.4 MHz away and rather easy to attenuate in the 45 MHz 1st IF. There's only a slight problem using stock 10.7 MHz IF components: Bandwidth of the whole 2nd IF might be around 160 KHz; less discrimination to nearby VORs and Localizers. A study of FAA sectional charts might be called for to check on potential interfering stations although those are assigned in regards geographic locations to minimize normal interference.

--- on the heady topic of "Re: Darlington Transistors At RF?"

Hmmm, what if the darlington is used in the bottom end of a cascode?
Use as the top end a high ft but low gain transistor. This way the
darlington collector voltage is stable and it relies more on the
common base fae for the gain limit, somewhat higher than ft, I think.
Darlingtons are only mostly good as emitter followers and DC switching
drivers anyways.

it is almost like the gunnplexer RX units we made around 1978-80,
wonder if the pcb's still exists for such receivers?

1642. Re: Darlington Transistors At RF?

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-03-19 00:45:47 UTC
From: Tom <noname@noprovider.nodomain>
Message-ID: <%CK_d.9315$mq2.5955@trnddc08>
Source record: 19825

The most significant problem with the standard Darlington connection is
the amplified Miller capacitance of the base-collector junctions. The
high gain of the darlington pair effectively multiplies this capacitance a
lot more resulting in poor frequency response (it won't go to VHF).
One approach is to tie the collector of the first transistor to an
AC-grounded
DC bias source, reducing this effect a lot.

This approach is described by Alan Grebene (founder of Exar) in his very
readable book "Bipolar and MOS Analog Integrated Circuit Design".

I agree about the 21.4MHz I.F. in a single conversion scheme. If the required gain is achievable, this is a very good way to go. I remember one of the Rockwell-Collins ADF receivers that had this setup.
As far as a 45MHz 1st I.F..... these crystal filters seem to be designed with a 455kHz 2nd I.F. in mind because a 910kHz rejection spec is given. I have used that scheme over the years with a diode ring mixer as the 1st mixer. I follow the mixer with a series L, shunt C as the second leg of a diplexer that matches the 50 ohm output of the mixer to the crystal filter..... The first leg being is a parallel LC tuned circuit that is in series with a 50 ohm idler resistor. With a reactance of the LC elements of around 47 ohms, the selectivity at 6 db is approximately 15kHz. The (2 time 2nd I.F. image rejection) is about 60dB when using four poles at 45MHz. I haven't done any in-band spur calculations with this scheme for the aircraft band but I think that with high-side injection it would be ok. Of course, if a 25kHz tuning step is used I am not sure how it would affect the phase noise of the synthesizer if a Fractional N topology wasn't used. I an NE602 is used as the 2nd mixer and just the I.F./ demodulator sections of a TDA1572 were used, the only adjustment required would be a trimmer adjustment of the 2nd LO in order to have a symmetrical adjacent channel response.

Hello Pete,

alignment instructions for the reference oscillator:

-With the TEST message displayed, press the MODE button. Connect a
frequency counter to TP2 (Local Osc).

-Adjust TC1 (on the control unit) for a reading of 45.00000 MHz +/- 20 Hz

alignment instructions for the heterodyne oscillator:

-With the TEST message displayed, connect a frequency counter to TP6 (Audio)

-Press the MODE button. Adjust TC2 for a reading of 3234 Hz +/- 10 Hz.

-Press the FAST button. Adjust VR1 for a reading 8 Hz above (3242 Hz)

-Repeat the procedure

My HF-150 (built around 1995) works very well after repeating that
alignment procedure a few times.

From: J M Noeding <la8ak@online.no>
Message-ID: <oa2p31dsd1vq70qrokvqfk0g39reu1gmp3@4ax.com>
Source record: 19830

The important is to limit the output voltage to 28V and have maximum
output voltage when input drop under ripple
One solution I can figure out is
http://www.noding.com/la8ak/12345/images/28vReg-4.gif

another more commonly found solution is
http://www.noding.com/la8ak/12345/images/28vReg-3.gif

the advantage of the first over the second is that the it needs single
supply voltage and the power fet can be mounted directly in chassis

I may be missing something, but neither one of the schematics shown in your link will work as you want.

For example, in link 2, you cannot get 70V out from a 24V AC source without some sort of voltage trippling or use of reactive components. Neither of these is present.

In link 1, you show a 24V regulater incorrectly wired and employed above its ratings.

Did you leave something out perhaps, like your input and output leads? Your post leaves me a little confused, but for me that's nothing new. :-)

You will also have to get power transformer to drop
your mains and that will add to the cost.

You can try to locate surplus power supplies,
linear type by Lambda, lambda/coutant, Nemic Lambda,
also switching supplies very inexpensive used surplus.
Telco power supplies also would be attractive.

Googling on "keyer paddle homebrew" or similar phrases should turn you
up numerous ideas.

About a minute of surfing turned up the following URLs:

http://www.geocities.com/n2uhc/paddle.html
http://www.njqrp.org/mbrproj/paddles.html
http://www.qsl.net/k5dh/paddles.html
http://kg8ih.cit.cwru.edu/w8edu/projects/franco-paddles.html

Google is your friend!

Thank you very much! I went through this alignment procedure and everything is fine now. I needed to replace the 4569 divider chip on the display board before I could do the alignment. This chip had a thermal problem.....after 15 minutes of operation, the BFO injection frequency would shift about 3kHz. After replacing the chip and going through the alignment sequency, I have a good HF-150. Thanks again!

Hello,
I got recently a (very) used HP-5341A frequency counter and it seems to have a problem with the high impedence input (which counts something even when shortcircuited or terminated to a dummy load), the other input appeat to be working good and also the internal 1 GHz source is beeing counted correctly. Does anyone have the user manual and/or (would be great) the service manual of this unit? Refunding the expense of course.

Thanks in advance

Possibly, the high impedance buffer amplifier is oscillating.
I was the project manager on the 5334B frequency counter,
which was derived from the 5334A. The 5334A used a
gold plated PC board. Gold plating requires that you first
nickel plate the copper. It turns out that the nickel is quite
lossy at RF, and the gold is less than a skin depth, so it
is transparent to the RF. For the 5334B, we initially used the
identical PC layout as the 5334A, except we went to the
then-new process called "soldermask over bare copper" (SMOBC).
AFAIK, the 5334B was the first HP intrument to use a
non gold plated PC board. Anyway, the front end oscillated
on the new boards, because the lossy nickel was no longer
damping out the oscillations. We had to insert a discrete resistor
at the input of the buffer amplifier to damp out a 100 MHz
resonance in a long trace.

I don't know for sure that the 5341 has the same basic front end,
but knowing how things went at the Santa Clara Division, it is
likely to be very similar. I never worked on the 5341 nor do I
have a manual.

Ive made a VUmeter for noise measurements in my EME system using a 50uA moving coil meter. By using a sheet of paper with the calibration curve on I can read the dB measurement. I want to do away with this and put the numbers directly on the meter display does anyone know of any software that can be used to make a good job of this.

> Hi Paul,
I assume you are defeating the AGC and measuring raw audio out. That
technique usually suffers from variations in system gain and the inability
to integrate well enough to take out noise fluctuations.
The "industry standard" for measuring sun noise in EME is the General Radio
1238 IF amp/meter.
I can easily resolve 0.1dB of sun or moon noise at 1296 with this piece.
Long term comparisons were impossible with the VU method, and looking at
less than 1dB was a guestimate.
These meters are often seen on EBay for $100 USD or so.

The only thing I can see is that it has indeed gold plated PCB, the
80 MHz amplifier is a little board with a few components and probably
all the integrated circuit are custom, so I have few hopes to debug it
without the schematic.

I'll probably return the unit to the former owner.

Thanks

Can anyone recommend a good source for 19" EIA rack mounted aluminum enclosure for electronic project? Also, this company should be able to handle small quantity order, and pre-punch square and round openings on the front and rear sides, and silk screen the lettering.

Has anyone else put their creations in a professional enclosure and had the openings made by others? Thanks in advance.

Considering the cost of shipping, someplace local to you would make
the most sense.

Check out the Thomas Register at a local library, or their online
version.

Hi,

I am not talking Linear but Switching power supplies.
(class B fcc type very low ripple and work very well)

Lambda has several lines of switching supplies, under 3 kilo !

http://www.lambdapower.com/products/ultra-flex-dc-series.htm

Lambda ultraflex, alpha or vega show up surplus
many times a week on auction ebay and trader lists.

These are expensive new but go for a lot less used or old stock,
newer models displaced this series.

I have a few I got for under $ 20 usd that were new in box.

Neither schematic shows the most expensive components: the transformer and filter caps.

If you have a 24VAC transformer and a full-wave rectifier you have something like 31 or 32VDC under full load. That's not a lot of headroom if you have brownouts etc to worry about.

It also seems that neither has any overcurrent/crowbar protection. If your pass transistor fails shorted and everything still works and nothing blows up... maybe you didn't need a regulator in the first place :-).

Tim.

In nearly 40 years years I have dealt with semiconductors I have never
experienced that crowbar has been a need for the power supplies used
on this side, but what I can say about many constructions seen, I
would use them without crowbar because they are sensible to RF, and
often not well designed in other ways
I usually have current protection, but for simplicity it isn't shown
here, I also considered to use a simple thing as an old fuse since
shortcircuiting the output hasn't really occured more than a few times
here.

I intend to use toroid transformer, and believe the output voltage
varies somewhat more than for a standard E-core transformer

1678. Re: Darlington Transistors At RF?

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-03-23 00:54:18 UTC
From: K7ITM <k7itm@aol.com>
Message-ID: <1111539258.034918.97150@g14g2000cwa.googlegroups.com>
Source record: 19712

Jan-Martin wrote, "perhaps not so much for RF, but I wonder why you don't see NPN/PNP combination for darlington transistors - with Vbe = 0.55-0.6V"

Actually, I think if you look at schematics of transistorized audio amplifiers, you'll find examples of about every practical combination of two and three transistors, used to build complimentary output stages. If I understand correctly what you are suggesting, I'm quite sure I've seen that configuration. In the 1960's and into the '70's, there were a lot of games played to try to pair up NPN power transistors with PNP drivers to get PNP-equivalents and NPN-equivalents that were as nearly symmetrical as possible while giving high current gain, since PNP power transistors weren't up to performing as well as the NPNs in that era.

Cheers,
Tom

1679. Re: VHF Aviation Receivers

Newsgroup: rec.radio.amateur.homebrew

Message-ID: <G6SdnVdIOo57WN3fRVn-gQ@comcast.com>
Source record: 19710

As a follow-up - I bought and assembled the really simple kit sold
by Ramsey - and described in detail here:

www.sentex.ca/~mec1995/aviarx/avrxkitc.html

I wasn't expecting much - but was really surprised! It works really well
and has provided a platform that I can hack to death without feeling
bad about destroying it if it comes to that...

I'm about 8 miles from Washington National (DCA) with alot of "stuff"
in between. With a lousy 21" wire, I have no problems picking up both
Potomac Departure and Potomac Approach (with the first I heard being
Air Force One coming in to Andrews AFB).

The only modifications I've made are to increase the supply to 12V (from
9V - per Jim Weir's comments) and to replace the worthless 10k varactor
tuning pot with a 3-turn widget salvaged from some old Tektronix gear.

The thing works great!

Now I'm looking for suggestions on how to "improve" it. My list includes:

Replace NE 602 with SA612A mixer and add "real" tuning via National PLL
and Minicircuits VCO.

Replace 10.7 Mhz. ceramic filter with 4-pole Xtal-based filter.

Replace MC1350 with MC1349 (per Len Anderson) and rework AGC.

Add serious LP audio filter to output of AM detector diode.

Throw away or rework "squelch" circuit - as it is makes lots of noise and
is annoying (loud pops when switching in and out)...

Get a decent (e.g. dipole 1/2 wave antenna).

It seems to me that after attempting to improve the RF section the biggest
gains are to be had in tweaking the audio stages - so that's what I'm
focusing on. Just for fun - alot of filtering, noise gate, compression,
limiting, etc. seem to be areas where I can really play with the thing and
improve the performance. I've been looking at both Analog Devices
and THAT components as a step short of going to DSP. I think some
real improvements can be made. The basic signal is there (certainly at
levels which are "good enough") even with such a simple receiver. I'd
like to see what can actually be done (keeping in mind that this is a
"learning exercise"..)....

Any suggestions appreciated! (And, yes, there are plans to tweak the
IF per previous suggestions!)...

Thanks,
Bill

Jim Garland, W8ZR used Buckeye Shapeform in the Miami, Ohio area for his
last project (silk screening and printing)
http://www.miami.muohio.edu/president/personal/w8zr/multicontroller/index.htm.

LMB Enclosures (California) does custom work - but I do not know what their
minimum order is.

There was an enclosure firm in the Ithaca, NY area that did this type of
work.

I can comment on the filter change.....the 10.7MHz ceramic filters
that are being used right now have an IN/OUT Z of 330 ohms.....a
crystal filter will have an IN/OUT Z of 3000 to 6000 ohms. It will work, but
you will need to match the impedances. If the crystal filter is not properly
matched, you will experience a deep nose in the response in the center of
the passband, and your insertion loss could rise sharply. If you are
interested, e-mail me directly and I can send you an Excel spreadsheet that
will calculate the values needed for a series L, shunt C type of matching
network.

Thanks Arnie.....a fellow in England sent me a scanned PDF
of the manual. You know, I've also got an AOR7030, but the HF150 does seem
to have a much better low end response remeniscent of the old Philco console
radios.
Thanks again!

Pete

1683. Re: Darlington Transistors At RF?

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-03-23 07:01:23 UTC
From: dumpjunkmailhere@yahoo.com
Message-ID: <1111561283.890471.90560@z14g2000cwz.googlegroups.com>
Source record: 19716

There are a few darlington transistors with an fT ratings of 20-200 MHz. IIRC, they are 2N6576, 2N6577 and 2N6578, all NPN devices with Pd's of 120 watts. I'm not sure if 20-200 is a misprint. Looks like one could get a lot of output with very little drive! Is anyone familiar with the 2N657x series? Are they suitable for VHF?

I guess it would have been handy if I'd posted the *correct* link
to the kit and schematic...8-) The kit was from Ramsey and it is
identical to the design and schematic posted here:

www.uoguelph.ca/~antoon/circ/aviarx/aviarx.html

As you can see it's surprisingly simple (and surprising how well
it actually works).

Thanks again for all suggestions!

> I have never experienced that
> crowbar has been a need for the power supplies

It's in large part an economic decision - why protect something if it doesn't have much value?

In many cases not having a crowbar means not really needing regulation.

Is your desire for regulation mainly to get rid of hum?

> I intend to use toroid transformer,
> and believe the output voltage
> varies somewhat more than for
> a standard E-core transformer

I've had good luck buying medium duty (several hundred VA rated) toroid transformers on E-bay and rewinding them for my own uses. You'll need something like 1000 VA, and I think these exist but haven't paid much attention.

It's generally easier for me to add/replace windings to toroid transformers than to unshellac a E-core transformer and rewind. Some toroids have shellac type coatings but many of the big ones are just kinda plastic-wrapped (not exactly heat shrink because heat shrink doesn't come in toroidal forms!), which makes things really easy.

Tim.

1688. ISO Pal 20L8 Chips and Burner

I had posted this elsewhere, and it has created some interesting feedback.
Based on Wes W7ZOI's Preogressive RX from the late 1980's. A wonderfully
balanced design to which I added some bells and whistles I like in a
receiver.
These are some shots of my almost finished 1980's theme HF receiver.
All stainless hardware, teflon wiring. Rock stable VFO, homebrew xtal
filters (5/2/5/0.5), selectable and defeatable AGC, notch filter, tone
control, QSK input,built in front end BP filters for each band, preselector,
AM/USB/LSB/CW.
Enjoy:

Dale -

Very nice. Looks like you built the RX .. that I am still designing since
1980 and reading Wes' articles. :-)

I see you used a 9 MHz IF.
Any particular reason that you used separate (LO) oscillators for each band
(rather than a single oscillator with switchable crystals) ?

The cabinet look a bit like some LMB enclosures.

Hi Greg,
I did not deviate a lot from Wes's original PR design- and that used a 9 MHz

IF. I also had a bunch of xtals for the filters- so just stuck with it. It also allowed the 49M LO to double as the 160M L.O.
F.A.R. circuits had the L.O. boards already made up, so I went with that. No reason I suppose, if one had an osc. that would paly well over the entire range w/ good spectral purity that a single L.O. and PIN diodes could not be used for switching. Would have saved on some SMA connex!
The side rails and cabinet, and matching speaker cabinet (not shown) are from a junker SB-303 I found on E Bay (have another for the mating TX once I recover). All the rest- front panel, subchassis, rear panel awere done in my machine shop.
I know of the LMB you are talking about - nice stuff, but hard to come by in larger sizes these days I suppose.
They were steel I thnk, whereas the Heath stuff is aluminum which I find a lot easier to machine.

Hi Mike,
The dial was the original inspiration for the receiver- it is an Eddystone
898 slide rule dial. 88:1 reduction, flywheel weighted and backlash free
silky smooth.

Dale: Inspirational. Very FB OM. I looked at all the pictures and found good ideal in all of them. Thanks for posting this.

Others have commented on the ugliness deficit in your project. Of course,
we're jealous, but I have to say that I've also found inspiration in the
much uglier circuit pictures that show up in SSDRA and (more recently), in Experimental Methods. I was reassured that the circuits in those books sometimes looked even uglier than some of mine. (And that's saying something).

So hey, maybe next time could you ugly it up a bit before taking the pictures?
;-)

Hi Bill,
Hey, I tried; I took the pix before cable lacing!
When I sent Wes some of the early pictures, he did comment on the "lack of ugliness". You guys are getting hard to please.
BTW, one of the thoughts that steered me along the way was to have a solid state Drake 2B with a few more bells. One thing I lack, but could be added is that wonderful Drake PBT. That is one advantage of the modular approach-experimentation down the road.

Dale

Very, very, very, nice job, thanks for showing your work..
I like the room inside to work on it..
The workmanship is commercial grade, what is your profession?
Did yiu say you've laced it, if so how about a pix?
The only thing that I see that I would do if I were building it is I would
swap the tone and volume as I like the volume right next to the tuning knob.
Where does one get an eddystone dial these days and how much?

Hi Hank,

There are a few things I would do differently too- unfortunately, that front
panel has too many hours in it (for me at least) to change. I learn on each
one.
I found the Eddystone on EBay and looking for another for the matching TX.
My professon is EE, but have a full machine shop and just enough knowledge
to use the mill and lathe.

Does anyone happen to have a copy of William Orr's "Radio Handbook" from 1997 that they'd be willing to part with (i.e., sell)? It's out of print, and so far the only book seller I've found that actually has a copy wants $95, which is a little too rich for my blood.

It's probably still under copyright protection, but otherwise I'd volunteer to scan the thing and turn it into a PDF if I could borrow someone's copy.

Surely because it works out to be simpler.

People often make the mistake that extra circuitry is bad because it complicates things, but the reality is often that extra circuitry simplifies things.

Back in the days of tubes, their bulk and filament current (or slow startup if you switch the filament) meant that one did give thought before adding another tube. It probably was simpler to switch crystals than switch oscillators, and compared to the cost of tubes and sockets, the switch was relatively cheap.

Once transistors came along, their size, low current and instant on meant the game changed. If adding another transistor in an IF stage meant that all the stages were running at a lower level, better to do. It added little to the cost, and pretty much nothing to the current drain.

If you switch crystals, you limit layout. You need that switch near the crystals (and in some cases may need two poles per position), or you need to use relays (I've seen it done in mods to tube equipment) or diode switches. Those diodes can often cause some problems, depending on choice and useage. Switching crystal oscillators means none of this applies, and the cost of the transistor and passive components is nothing compared to the cost of the crystal.

This is a theme of some of Hayward's work. Various times, he's described transceivers, and not only is he using separate IF strips for receive and transmit, but he's got a separate IF filter for each function. His reasoning is that it makes the chain cleaner by not having the switching. Given the cost of commercial filters, I'm not sure that's the best choice, but certainly there is a tradeoff. If adding a few dollars for an extra RF stage rather than switching tuned circuits requires a cheaper switch, or makes it easier to do the switching, it may be worth spending those few dollars rather than fuss too much.

Jerry Vogt (I"ve spelled that wrong) who seemed to be connected with Hamtronics (at least, he wrote about their stuff for Ham Radio magazine) pointed out in an article about preamps that a manufacturer needs to cut costs. They skimp on parts because any single part saved is

multiplied by the number of units built. But a hobbyist building a single unit doesn't have that multiplier. If they toss in an extra bypass capacitor here, or build each stage into a metal box for shielding, the cost is right there. They don't have to worry about 10,000 more capacitors, or whatever.

There was a 1997 one? I thought the last one was Edition 23, which
came out in 1987. Certainly when I saw it advertised after
that, it was still showing the 23rd edition. And it's not as
good as the ones previous to it. I'm not sure if it took a dip,
or if it's just that there was little different that interested me
from the previous few editions.

Lindsay Publications used to have a 1936 edition as a reprint, but
that's out of print. Though of course back then it was under the helm
of Frank Jones.

I "think" it was Howard W. Sams (can't recall for sure) who was having a "clearance" sale on those books a few years back. I got one for about $20 or so. Nice book. I could swear from all I've read, the 23rd was to have been the last. Maybe they snuck another one in.

Try Amazon.com to see if they have it - if you've not already tried there. Maybe even the store called "Half Price Books" if there is one in your area. Barnes and Noble or Waldon's may have it, but they're not that cheap. OR too, you could go to the Howard W. Sams Web Site to see if perhaps they have any left.

I just checked, mine is the 22nd edition. Oh well!

Cool stuff. Way cool.

Just trying to sort out the bandswitching from the pictures:

Antenna input is switched to one of six bandpass+optional RF amp boards. It looks like the antenna switching is by the black relays in the back?

Eight bands, six band boards, a couple of the bands must be close enough together that they utilize a common board? Or maybe the IF *is* one of the bands...

There appears to be a preselector knob on the front, how does this go into the bandpass/RF amp boards.

The output from the RF band boards is then brought to some sort of combiner board that I cannot make out anything but a bunch of SMA jacks on. Is there switching there too, or (because of power switching to the RF boards) is this just a simple combiner?

And that Eddystone dial is to die for. Oh, man.

Tim.

Actually, there is a 1997 reprint from the 23rd edition originating from 1987.
The reprint was done by Butterworth-Heinemann.

The impressum has the following in it:

"The publisher of this book offers special discounts on bulk orders
of this book. For information, please contact:
Manager of Special Sales
Butterworth-Heinemann
225 Wildwood Avenue
Woburn, MA 01801-2041

Tel: 617-928-2500
Fax: 617-928-2620"

Good luck!

There were usually multiple printings of each edition. It only came out
every few years, while the ARRL with an edition once year just prints a new
edition rather than run a second printing.

My 23rd edition is a 3rd printing, from 1989.

> Hi Tim,
An excellent job of sleuthing- I never could have done that.The RX is
essentially an 80M RX with xtal controlled converters for the other bands.
You are correct, the rear board switches the antenna to one of 6 front end
BP+LP filters- 10M 28-28.5 and 28.5-29 share a filter and 80M is bypassed
through this section directly into the preselector (which works on 3.5-4MHz
only). The board along the power supply side switches the filter outputs
into the 1st mixer. A relay on the output of the 1st mixer selects either
its output (3.5- 4MHz) or the 80M signal directly from the antenna. This
signal then goes to the preselector- which is a very sharp tunable BP.
The relay board on top of the chassis toward the rear selects the
appropriate L.O. and routes B+ through the coax to the L.O. 160M and 49M
share the same L.O. but different input filters.

Again, brilliant work on your part.

That's very well said!

The "optimum" design is, as you say, very much a matter of the particular situation. In my career doing circuit design, I've worked for a company where products were custom or nearly custom -- a production run of 10 was a big deal. In that situation, if I could save half an hour of design time by using a $20 part instead of a $5 part, it was a very good trade. I've also designed a product for a mass near-consumer market. There, a week of extra work spent in getting a few pennies out of the production cost was worthwhile. We all have to remember that:

1. There's no one best way for everybody, every project, or every market or situation.
2. What's best for the mass manufacturers, or for that matter another homebrewer, isn't necessarily the best for us.
3. The best way to do a design is constantly changing, as both techology and our own situations (e.g., the amount of time and money we have) keep changing.

Design is a creative process, and there's a lot of art as well as skill in it. Finding a better way to do something requires both, and knowing the appropriate time to declare it "good enough" requires art, skill, and discipline too.

> details including source code.

Thanks for all the suggestions. I found the QST article on the switched automatic tuner at LDG sold (AT-11). The source code was not published and I think the ARRL has a new policy requiring source code (in most cases). The article does hint at the algorithm. It was written in assembler on a Motorola 'HC11.

I am interested in building a similar design and playing with the tuning algorithms. I need a suggestion for a microprocessor/microcontroller. I am most experienced with the Motorola 'HC08, PIC, and Rabbit Semi 2000 series. I think I would rather code in C. So here are the basic specs for the processor:
1) low cost C compiler/IDE
2) at least 28 available general I/O bits
3) built in 8 or 10 bit A/D (2 channels are enough)
4) low cost development board or easily constructed one.
5) 16 bit or larger counter

What is the easiest way to have the tuner measure the frequency? Should I just put a pre-scaler in front of a digital port and sum pulses over time?

What do you think of this idea? Have the tuner control the transmitter. Use the combination to completely characterize the antenna across each band of interest. Then select the tuning "instantly" based on a large frequency-based lookup table. With enough table space, you could create a table for each antenna and each band. This assumes that none of the programmed antennas changes much over time.

Hi, all concerned:

Belated thanks to past suggestions, due to which I've been studying and
using trial downloads of the following:

1. tina.com

2. beigebag.com

3. 5spice.com

4. cirsim http://www.bells-hill.freeserve.co.uk/

5. circuitmaker

6. electronics workbench

7. pspice orcad.com

Prices range from $20 to $2.3E3.

Anyone out there have any of the above for sale?

TIA &

Most of the autotuners use a Lookup table for "Instant Tuning" once
a Frequency has been tuned previously. This causes a lot less wear on
the Cap Contact Points.
1. Measure Freq by looking at period.
2. Lookup tuning canstants in table. If no data jump to tuning routine.
3. Set tuning constants and measure Reflected Power and Phase.
If above Set Level jump to tuning routine. If below, end/shutdown.

Run tuning routine at less than 5 watt level, will also save contacts.
All you need is enough power to allow the period to be measured and for
the Phase and forward and reflected power levels to be sampled.

Though tangential to your request, I'd point out that there are some simulators that are good for specific problems. RFSim99, for example, is a wonderfully simple and useful little program for looking at linear RF circuits. It includes a Butterworth and Chebychev filter design tool, attenuator design, L/pi/T match tool, inductor, capacitor, transmission line, splitter, and coupler tools, and an L/C/f/X calculator, in addition to the circuit simulation/two-port network analysis in the main window.

Cheers,
Tom

1726. New Program RJELOOP4

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-03-26 06:26:16 UTC
From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <d22va8$1tb$1@titan.btinternet.com>
Source record: 19659

This program predicts approximate performance of general purpose, multiband, horizontal loop antennas of given perimeter of loop. It is not intended for precision predictions of operating data.

A loop is a continuous wire without loading coil or capacitor. It can be of any shape provided the area enclosed by the loop is not less than 2/3rds of that of a circle of the same perimeter, ie., it is not too irregular.

It is the sort of antenna which is forced on the amateur by the shape of his back garden and the pre-determined location of trees, poles, buildings or anything else from which an antenna wire can be suspended.

Analysis includes a high or low impedance feedline, a choke balun and an L-tuner. The antenna is most efficient when the perimeter is a whole number of wavelengths. It is least efficient when the perimeter is an odd-number of 1/2-wavelengths. But operation is not limited to being at, or near to, resonant frequencies.

Download in a few seconds program RJELOOP4 from website below and run immediately.

I really enjoyed the message thread sparked by the pictures of
Dale's very FB HB RX. We need more of that kind of discussion...

Here is what I've been working on in London:

40 meter DSB phone HB: UK hams recently got a doubling of their 40
meter
freq allocation and can now go up to 7.2 Mhz. I built a simple 40
meter DSB
transmitter. Solid state. VFO. Built it on a wooden cutting board
(almost
a real breadboard. Puts out about 2 watts. I run it into a heavily
modified
Ramsey kit linear. Then to a HB balanced tuner, TV lead up to the
inverted
U dipole. Works fine. Lots of fun. I use it with my Drake 2B, but
plan on
pressing into service my HB "Mate for the Mighty Midget" RX (see web
site)
(I have a 455 kc filter that I'll install eventually -- right now it
is very broad).

17 SSB phone:
I have a HB 17 meter SSB TX (see my web site). I' also use it with the
2B, but changing bands is a pain. So I'm building a dedicated RX for
17.
I have a Doug DeMaw "Barbados" reciever (someone else put the
components on
a "Circuit Boards Specialists" board. It has a 5Mhz ladder filter that
I've
broadened for pnone. I tried running the VFO at around 13 Mhz with
varactor
tuning, but it was unstable, so I'm going VXO. With 2 rocks in the 23
Mhz
range I shoud cover the phone portion of 17.

More later... Any comments or suggestions? How about following
Dale's lead and posting updates on projects?

>
> Hi Bill,
I have trouble keeping up with where in the world you are, but visit your site regularly to see what you are up to.
I would encourage others to brew their own xtal filters. uP xtals are cheap enough today that you can buy a pile and match up what you need. W7ZOI's articles on crystal filters takes the mystery out.
Probably the most difficult part is characterizing individual crystals so you can plug in the numbers. I use an HP network analyzer, but Wes also shows a test jig for doing this. Alternatively, N2PK's VNA will do an excellent job. In the end, you can make better filters than you can buy- and for a heck of a lot less $$.
N2PK recently sent me 2 WAV files- one recorded with the 1000MP stock 250 Hz filter; the other with a homebrew 250 Hz filter- it took no imagination to discern which one was cleaner.
Now, I'll go have a look at Bill W0IYH's site.

Dale: I was faced with doing the complex analysis of the individual
crystal
parameters when I was building my first superhet (W1FB's "Barebones"
aka
"Barbados" RX). I just skipped all of the analysis and used the same
capacitor
values that Doug had used in his version. I'm sure my filter's
passband wasn't nearly as pretty as it could have been, but it
definitely produced the
desired "single signal effect." I was happy.

As I mentioned in the earlier post, I have an 80/40 meter tube type RX
(Mate
for the Mighty Midget"). It has a 455 kHz IF. This makes homebrew
filter making difficult! I tried, but crystals were hard to come by
in that freq
range. In the end, I threw in the towel and just used a 455 Khz IF
can
in lieu of the filter. Great for listening to AM! But now I want to
narrow
it down a bit, so I'm thinking about yanking out the IF can and
replacing
it with a commercial 455 kc filter from the junkbox. I need to figure
out
how to handle the impedance matching issues (input and output).

At the risk of being a spoil-sport I wouldn't even contemplate using the rig whilst driving - just as I wouldn't use a mobile phone whilst driving. Riding a motorcycle or driving a car needs your full attention. <g>

Of course, modifying it will void its Part 15 certification (and I
assume it is Part 15 approved) and open you up to the wrath of the FCC...

Hi Bill,

I too built the Barbados RX- don't know what happened to it though.
Have you thought of using a Murata ceramic filter in your tube RX?
They make a 4KHz unit for under $3. Not CW selectivity, but I'll bet it will
be an improvment over what you have. Typcial Zin and Zout is around 1K.
Although I have never tried it, I wonder about the possibility of brewing
your own ceramic filter from some of Murata's 455KHz ceramic resonators.
Although not the Q of a quartz crystal, it may be worthwhile. I have some
here and think I'll put one on the network analyzer and see what
characteristics I get.

Dale: Wow, another Barbados RX builder. That was my first successful
superhet project. I now have the one I built (still on 20), and this
morning
I got another one (the one built by someone else on a factory-made
board)going on 17 with a VXO. I have a THIRD partially built Barbados
RX board. If this
keeps up, I'll soon have a BBRX museum.

As for the tube RX, I have a Toyo Communications CM filter. Markings
look good:
"445 -- 2.4 -- C" Now I have to figure out how to work this into the
existing
RX circuitry. Time to look through some mid-'60s handbooks and QSTs.

Dale - regarding homebrew crystal filters - I wonder if you or any others here have looked at Elecraft's crystal filter implementation in the K2? It's built with discrete crystals and the bandwidth is variable over a large range. Haven't seen that design exploited elsewhere, but don't know why. It sure works well.

I've done this with ceramic filters in tube circuits. You definatly
need to match the impedence to the tubes wich is high both for plate
and grid. What I did for that was to use a transistor IF can, filter,
IF can wired so the high impedence side was to the grids and plates.
Worked very well in a tube RX like the mighty midget.

For transistors the matching for those filters is IF can to get the
high collector impedence down to 1k range then the filter into the
base of the transistor. FETs get treated like tubes.

I recently purchased an old crank-up motor driven 60 foot tower that I would hope someone could id for me. The motor belt drives a gearbox, which turns the cable pulley. It has a approximately 1 foot by 18 inch control box which has two high current relays and two glass contained relays. The glass-contained relays are in old 8 pin tube sockets.

The tower, itself, is in good shape. I would like to re-build the control circuits and out the tower in service. Any information anyone can give me on this tower will be greatly appreciated. See at www.winlyn.us/tower.jpg.

This may be caused a lack of smoothing of the supply voltage (assuming you are in the US). Lots of peaks suggests FM modulation.

That's it Bill! Amazing. Hopefully I placed the Dc-DC converter inside that
shielded enclosure. Glad it has a good home.
I believe that board was from A&A Engineering- seem to recall they supplied
for QST back then. That design was a very robust RX. Doug (?) had sent me
the companion TX article before release- but I never got around to building
it.
How many countries has that RX travelled to now?

1768. SWR meter, inline, non-resistive, led

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-03-31 16:27:19 UTC
From: John Smith <assemblywizard@gmail.com>
Message-ID: <d2h8da$d5u$1@domitilla.aioe.org>
Source record: 19601

I am looking to construct a SWR meter which can be left in line and consumes negligible power (just to light a led or two and associated, minimal, losses of transmitter power.)

I had seen such a schematic years ago. Drawing a mental picture, from what I can remember, a wire ran down the center of a tube on a couple of insulating spacers (washers) in a concentric configuration.

A small hole in each end of the tubing allowed an insulated pickup turn to be run adjacent to the wire in the tube--exiting the holes in the sides of the tubing, this picked up sufficient reflected power to drive the led(s) and give an indication of SWR (led(s) dim or out at 1:1, or near.

Anyone got that schematic/construction details or, one of a similar unit to construct?

This unit was inserted in the coax line to the antenna.

Warmest regards,
thanks in advance
--
Hay, if'n ya'll cun't konstructivly partecipete in this har disscusion, haw aboot speel-checkin it fer me?

From a purist standpoint there can be problems:
1. Asymmetrical skirts
2. Changing IN/OUT Z with BW
3. Shifting center freq as the BW is narrowed (> capacity loading)
4. I am guessing here, but I would think the group delay would suffer at one
end or the other
5. Passband ripple can become excessive as BW is increased.

I looked at this approach, along with a method described in QEX last year
for dealing with the center freq shift, but came to the conclusion that I
could design a much better filter if I optimized each BW- even though it
took 3 filters.

One aspect of filters that has long been either ignored or overlooked (
even though W7ZOI details it in EMRFD) is group delay. A friend (N2PK)
recently sent me 2 WAV files of a Yaesu 1000 stock 250Hz filter and his
homebrew 250 Hz filter. The difference was remarkable- his filter was much
cleaner and crisper sounding, no ringing. Great care was taken with group
delay in his design.

> Nuc_em2000@hotmail.com
> thanks Ken

It can be done.

You need do:
1) match the pin wiring
2) match the microphone impedances (although this may not be important)
3) match the gain of the microphones with an attenuator or amplifier.
4) supply power to the computer microphone if it is an electret type.

You will need to get the microphone connector wiring from the manual or from opening the microphone. If your computer microphone is electret, it will need 3 to 12 volts of DC to operate the element. I don't know if CB manfacturers put a voltage like this on the microphone connector.

Anyway, it is not straightforward, but it can be done. I did it for my Midland 2 meter rig. I embeded a speaker and tiny electret mic in the foam of my helmet.

I'm looking for a NEMA type 4 box or equivalent. New one are a bit pricey. It must be weather proof. Small holes OK, since I could weld pathes on to keep it watertight. It will be for my 432 beacon and will be mounted up on a tower (up to 200 feet above ground). Prefer metal. Size needed would be about 12" X 12" X 6" or so...

Thanks,

Scott

Yes, they have a heavy rubber seal under the lid, and the lid is held down tightly. They're made of heavy gauge steel, which might be better (it's shielded) or worse (it's probably heavier) for your application than the plastic box others have recommended. They come in at least a couple of sizes and are relatively inexpensive. Think I paid $15 or $20 for some fair sized ones a while back. Considering their objective of keeping ammo free from corrosion and excessive moisture in virtually any environment, they seem to be a viable choice for an outside enclosure. You might want to seal it up when exposed to dry air and possibly enclose a dessicant, also, to reduce condensation problems. Some of the plastic boxes have a one-way valve to let air out but not in, which might be an advantage.

I don't have any real experience with keeping a weathertight box outside for an extended period, though. It would be good to get some opinions and advice from people who do.

Win;
The tower resembles a US Tower with the retracting cable which was used on some but not all models. I would assume the glass relays are in fact time delay relays used as part of a remote control circuit. I beleive this is the case because the US Tower controller without the remote control option can be fooled into failing to reverse direction if the up/down toggle is reversed while the motor is still moving. So if remote control were used there would need to be a delay when switching direction.

As a part of your refurbishment you should replace each of the cables and inspect/ replace the pulleys. The pulleys have bearings which can fail and cause the cable to bind leading to failure.

Do keep in mind that the tower is a pretty dangerous piece of machinery even if you are simply working with it laid out on the ground as the sections can trap your hands if they move while you are working on it. Once you get it erected, there is a lot of force on the cables and steel and so becomes even more dangerous to work with.

You should study the assembly of the tower sections and cable arrangement carefully and create drawings and label each part and cable before disassembly. Feel free to e-mail me as I have refurbed one in the past and it worked out pretty well.

Pricey? Not the smaller ones. I've got a pair of 12x12x6's in my van that ran about $30 or so.

No, they're not metal... They're a sort of plastic-fiberglass composite. However, installing a copper 'Faraday cage' internally would be a simple matter of cutting and bolting in some copper sheets. They do, however, meet the full NEMA-4X specifications for water resistance and other environmental nastiness.

If you decide to pursue such, Platt Electric Supply (nationwide chain) has them.

Happy hunting.

"I" am not up on the "NEMA" specs as I don't do a lot of that sort of
thing... I wish we were closer, as I have a heavy metal gauge outdoor -
weatherproof box about the size I've been seeing mentioned..... I am selling
it for $50 not counting shipping. It has some weight to it, so not sure what
it would cost to ship.

You can cascade NPN-PNP transistors by connecting the collector of
on transistor to the base of another (of different polarity). I recall
a circuit that used two pnp and one npn transistors in a three way
cascade, the final transistor was a PNP power type (all Ge).
It used 2n107, 2n170, and 2n301 transistors as a simple audio
amplifier for a phonograph.

Composite would be fine. Mouser has them in , I think, 8 X 10 X 4 which would work, but they're somewhere around 60 dollars. I'm a cheap b@st@rd. $30 is about max I want to go for a beacon box...I'll scout around some more....thanks for the tip.

Gary and Ken -

Actually, IF you desire an LMB / Heath SB-series / Collins S-line look

My best suggestion is to find the junker SB-400 /SB-300 and S line junker
chassis on eBay, such as this item number: 5764132119
http://cgi.ebay.com/ws/eBayISAPI.dll?ViewItem&category=4671&item=5764132119&rd=1&ssPageNam
e=WDVW

It's a great starting point and you can use the cutouts OR fill the cutouts
with aluminum or steel sheets
available from K&S Engineering (local hobby store) or your local hardware
stores (Ace; Lowe's; Home Depot)

Have you got a decent scrapyard or recycling center? The local
scrapyard has a bunch of used NEMA boxes but the shipping would be high
from here. I've seen stainless and painted steel in several sizes. The
only small metal NEMA box I have right now is⋆" ⋆ 10" and 4" deep The
next one is a lot larger than what you are looking for.

I've been told there is a way to make a circuit board with a computer printer, i.e. make the traces on the back side. Can anyone tell me about this?

Thanks for your help.

Do you mean the 'press and peel' resist film?
You print your pc layout on the film using a laser
printer or copy machine and then iron the film on
to the pc board. The toner becomes the resist, and
you then etch the board in the usual manor.
You can buy the stuff from www.techniks.com

There are several.

One way is to laser-print the resist pattern onto a transparency (or laser-print into paper and photocopy onto a transparency) and then use the resulting transparency as a photographic mask, exposing a piece of photosensitized PCB material to UV light through the mask. The exposed photo-resist is then developed (chemically in many cases) and the unexposed portion is washed away (or vice versa - depends on the type of resist) and the board is etched.

Another way is to laser-print the resist pattern (mirrored left-for-right) on a specialized sort of coated paper. The PC board material is cleaned thoroughly, the printed paper is placed on the board toner-side-down and carefully ironed onto the board - the resist melts and sticks to the clean copper. The board is soaked in water, and the coating on the paper releases the toner/resist and the paper washes off of the board. The board is then etched. There are commercial papers made for this purpose, I've heard of people using some glossy-surfaced inkjet papers, and some folks even make their own by brushing a liquid gelatin solution onto smooth paper.

It's also possible to use a flatbed plotter, with a special pen, to draw resist patterns directly on PC board material.

The "usual" way of getting a WWVB receiver chip is to buy a cheap WWVB clock and rip out the chip and antenna. Some have external chips/antenna connected via cable already.

A web page showing how to do this with a commonly available Sony WWVB clock is at:

http://www.leapsecond.com/pages/sony-wwvb/

Tim.

Hello Tim,

> The "usual" way of getting a WWVB receiver chip is to buy a cheap WWVB
> clock and rip out the chip and antenna. Some have external
> chips/antenna connected via cable already.

Agree. Many like the Sony even contain two crystals. These alone can
cost more than a whole clock.

But if it's a matter of pride you can build your own even without any
special chips. When I was a kid I built a receiver for DCF in Europe. No
crystals, only a few transistors and 741 opamps. It worked great, except
that I didn't have a PC or anything to decode the signal with. It was
just the detected pulses but these came through nice and clear. With
today's opamps you wouldn't even need any transistors to do it. A decent
quad can be had for 50c while I paid a whopping $3 for a single
re-labeled 741 of rather dubious quality level.

Regards, Joerg

I think this is the stuff. Let me get this straight. It's actually the toner from your laser printer which transfers to the copper on the board. The toner is the resist. Is that correct?

Thanks

I'm familiar with the photosensitized PCB material and UV light method.
But this is hardly an at-home kind of thing. I think I was looking
for the second method you mentioned.

I make my PCBs at home using that method. It works much better than toner
transfer for me, and doesn't take much longer.

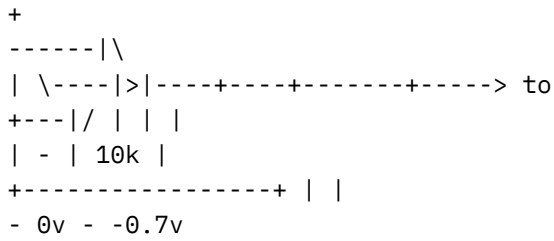
1823. Advanced VHF Wattmeter

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-04-04 13:16:12 UTC
From: Stewart Bryant <stbryant@cisco.com>
Message-ID: <1112620397.901444@sj-nntpcache-5>
Source record: 19556

I am thinking of building the "Advanced VHF Wattmeter" by
Bob Kopski K3NHI published in QEX May/June 2002, and was
wondering if anyone who subscribes to the NG understands
the function of IC2a.

This is a voltage follower with a diode in the feedback
path, which as I recall is a precision rectifier. It is
then followed by a biasing circuit, which seems to fight
against the low impedance output of IC2a, which again
I don't understand the need for.



IC2a is interposed between the output of the AD8307 log amp
and the input of the DVM.

The AD8307 is runs between ground and +5v, and so
will only produce an output of between 0 (-80dbm) and 2.5v
(+20dbm). I don't therefore see the purpose of the stage
of the biasing arrangement.

Surely all that was needed was to take the output of the
AD8307 into the potential divider to set mv/dbm and
the to set the bias on the -ve side of the DVM to get
the 0dbm offset.

Any ideas?

Thanks

Stewart G3YSX

1824. Spectrum Comm. SCT-110 Schematic

BW> I'm familiar with the photosensitized PCB material and UV light
BW> method. But this is hardly an at-home kind of thing. I think I was
BW> looking for the second method you mentioned.

Sure, it is doable at home. One method similar to the above
transparency is to simply print the pattern on thin tracing paper and
then oiling it. The oil makes the paper transparent and allows
exposure.

The most difficult but important thing in PCB making is to get an
accurate exposure time for the sensitized PCB. The way to determine
this is either with a calibrated UV source, or to expose a test strip.
Use a thin 1/4 " strip of PCB and cover it with a cardboard sheet,

slide the sheet back exposing 1/4" at a time. Use 1 minute increments. The last segment uncovered will be 1 minute and the 1st will have the longest exposure. Then develop the strip and note which was the best exposure time.

I've even made exposures in the Sun. Just one problem I noticed with this method is that the Sun moves and tends to undercut the traces, so in the case of a transparency the toner side must go against the PCB surface as otherwise the small gap allows the Sun's changing angle to leak under. This doesn't happen so much with a fixed UV lamp. It helps to do this at Noon so that the Sun's angle changes less and reduces exposure time. It takes about 10 to 12 minutes in the midday Sun and it takes about 2 to 3 minutes with a sunlamp, clothes drier UV lamp, etc... It's a learning experience, good luck!

"The unforgiveable sins this earth must confront and overcome are
Nationalism, capitalism, and hoarding. The idea of every nation
should be forgot, price should be struck from the commons, and
princes should be seen for the devils they are. The sins include
our church, secret societies, and other religions which make of
the spirit of God a divide."

Last rites declaration of Ioannes Paulus PP. II (Karol Wojtyla)
2nd April 2005

--
Three degrees of latitude
reverse all jurisprudence; a meridian decides the truth. Fundamental laws
change after a few years of possession; right has its epochs; the entry of
Saturn into the Lion marks to us the origin of such and such a crime. A
strange justice that is bounded by a river! Truth on this side of the
Pyrenees, error on the other side.

Men admit that justice does not consist in these customs, but that it
resides in natural laws, common to every country. They would certainly
maintain it obstinately, if reckless chance which has distributed human laws
had encountered even one which was universal; but the farce is that the
caprice of men has so many vagaries that there is no such law.

Theft, incest, infanticide, parricide, have all had a place among virtuous
actions. Can anything be more ridiculous than that a man should have the
right to kill me because he lives on the other side of the water, and
because his ruler has a quarrel with mine, though I have none with him?

Doubtless there are natural laws; but good reason once corrupted has
corrupted all. Nihil amplius nostrum est; quod nostrum dicimus, artis est.40
Ex senatus--consultis et plebiscitis crimina exercentur.[41] Ut olim vitiis,
sic nunc legibus laboramus.[42]

The result of this confusion is that one affirms the essence of justice to
be the authority of the legislator; another, the interest of the sovereign;
another, present custom, and this is the most sure. Nothing, according to
reason alone, is just itself;

1828. Help please choosing transmitter/reciever pair

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-04-04 17:20:56 UTC
From: Eric R Snow <etpm@whidbey.com>
Message-ID: <hpt2511f3iiqk8f7vrk7hcojakkio99nqn@4ax.com>
Source record: 19560

Greetings Group,
This question may be better placed on the radio group and I'll post there too. And so here it is. The question: I am looking for a a transmitter/reciever pair to use for transmitting data 20 feet. The reason for the radio interest is to avoid cables. I've been to the Maxim and Linx websites. It seems like the Linx devices won't work because I think I need to transmit two data streams. The data would be coming from a chinese digital scale. The pinout for the scale is at this link:
http://shumatech.com/support/chinese_scales.htm
The solution to the transmitter reciever combo must be low cost, low power consumption, and small size. The antenna needs to be flat and enclosed in the transmitter case. Please, if anyone has any suggestions, or can tell me what to look for, I'd really appreciate it.
Thanks,
Eric R Snow

Hello Albert,

> I was attracted to the Temic wwvb/dcf77 receiver chips because they
> draw 30 microamps...so, a receiver that draws 4 microamps is indeed
> low power and is very promising.

AFAIK many "atomic clocks" listen to WWVB briefly and then turn off the receiver again. With a very low on/off duty cycle the power consumption of the receiver wouldn't matter so much.

I have some packs of 22 AWG Teflon insulated, silver plated, stranded wire. It is in packs of five 50 foot rolls (250' per pack). Should be able to get five different colors per pack. Sorry no choices of colors. No other gauges available at this time. This wire is rated 200degrees C and 600V. great for both tube and solid state equipment. It won't melt or shrink or stink when you solder it :))

The deal is for Three Packs (3 x 250ft or 750feet total.

Total cost is $25 including shipping. This is for lower 48 States.

Email to reserve. I have to package it. Shipping within 48 hours. 2-3 day shipping time typical.

qrz.com address OK. paypal available.

73,

Jim n2go

Actually techniks makes two types. The press-n-peel wet uses only
the toner as resist. The press-n-peel blue adds an additional
layer of blue 'stuff' that is released by the heat of the fuser
wherever the toner gets deposited. I think the blue stuff is
better for pc boards, but the wet stuff makes a great way to
label panels! They cost the same!

Does anyone know what kind of AC voltage a Microwave oven transformer would put out? Are they center taped or just a single coil?

I need a replacement for my homebrew 3-500z single tube amp. I only used it for low power AM and I don't need "maximum voltage".

They are a single winding on the secondary and not designed for
continuous use. You would have to switch the primary to prevent
overheating when you aren't transmitting.

From: John Smith <assemblywizard@gmail.com>
Message-ID: <d2sp5vjgk1@domitilla.aioe.org>
Source record: 19568

I have gleaned 1.5KW commercial microwaves for their transformers (they had timers which maxed out at 1 hour!), removed the secondary and replaced it with heavy copper wire to make 13.8 V high amp supplies for mobile linears converted to shack use.
The ones I have come across--where I bothered to measure the voltage of the secondary, were 3000+ V, as I remember 3300-3500 V.
Two matched transformers should be able to serve as a center tapped transformer without much re-engineering.
In amplifier use, a transformers 50% duty cycle specs should be sufficient--I wouldn't be surprised if they could serve well in amps (and it never hurts to make sure the xfmr benefits from a fans output.)
The only red flag which pops up in my mind is if there would be sufficient isolation of the primary from the secondary at low freq. rf., if not, something there could probably even be worked out (and, my worry may be false to begin with.)
In extreme cases, a heat sink could be fitted to the exposed section of the top and sides of the core (heat conductive epoxy would work.)
And, hey, if I guy gets long winded and smokes a xfmr, a trip to the dump for a replacement is cheap!
Take care, those transformers can pack a lethal wallop!

Regards,
John

Hi Ed,
I have an 1N34 (or perhaps it is an 1N60) that I will ship you if you post me your address. As far as growing one, I don't know about that, but would like to hear if anyone posts you that info.

I have missed that. What are the problems?
Even the power supplies I have made which power 1500+ liners have held up fine. I do notice they seem to run a bit warmer than their expensive counterparts.
I am convinced without arguement that their efficiency is lower than a more conventional xfmr--one reason--microwaves are usually only in operation for short periods of time.
However, all I can see which might be happening is my electric bill is a few cents higher...

Regards,
John

I don't know about growing a crystal, but the most popular choice is
Galena. Iron pyrite and some other minerals also will work. Heck, an
old Gillete "Blue Blade" or other thin double edged blade will work to
some extent, ala the WWI foxhole radios.

One of the nurseries here in Atlanta sells minerals for decorative
purposes. You can order a Galena crystal already mounted, as well.

Acouple of web sites to check out are
The Crystal Set Society <http://www.midnightscience.com/>

Crystal Radio Resources <http://www.thebest.net/wuggy/>

The key phrase to search for is "magnetic shunt". Typically the magnetic shunt consists of two extra blocks of laminations between the primary and secondary bobbins. This has been added to give the transformer a current-limiting characteristic, which is necessary to power a magnetron - but is exactly the opposite of what you need for normal vacuum tubes.

In many oven transformers, the magnetic shunt blocks can be driven out with a large punch, to leave a more normal-looking transformer.

The not-so-good news is that you're still left with a transformer that has a very high secondary voltage and rather high secondary resistance, which will give poor voltage regulation in typical amateur use. Also one end of the secondary winding is usually grounded to the core. Even if you can get to the grounded end to disconnect it, the insulation close to the core is not designed for typical full-wave bridge applications.

Some people have had limited success with a pair of identical transformers connected as a "centre-tapped" winding... but remember that in two separate transformers the core magnetization by the DC components will not cancel.

It all seems like a lot of effort for rather poor results.

> two crystals. These alone can cost more
> than a whole clock.

Of the longwave radio frequencies used for time standards, 40kHz (JJY, Japan), 77.5kHz (DCF, Germany) and 60 kHz (WWVB and MSF) crystals are off-the-shelf items in the Digikey catalog at less than a dollar each. I'm guessing their easy availability is because they are commonly used in real receivers.

I've always noted with some curiosity that 77.503kHz, 60.002kHz, and 60.005kHz are off-the-shelf crystals too... used in a direct conversion receiver for DCF/WWV to 3Hz, 2Hz, and 5Hz carrier-detect frequencies maybe?

Tim.

Hi guys, just joined this group and a bit at risk re-starting a finished threads. I am curious to know if there any radio designs known here for an analog JVC tv-tuner, pinouts UB, TV, VHB, AGC, VLB AFC, MB and IF, which I have at hand. The board on which the tuner is mounted also has a AN5111 and a SAW-filter, even a testpin Audio. Goal is to make a 2m radio, the quick and easy way. It looks like everything is on the board already?! Found a Swedish website, but there didgital tuners are used.
Regards,
Dirk

A silicon diode will work, it won't be as sensitive but you can get one
at the local Radio Shack (they carry germanium diodes off and on, so
they may have some).

If you're using germanium diodes get some spares -- I've found them very
susceptible to lightning strikes, at least in the circuit that my son
and I built.

Yes, I see.
I never attempted to get the laminations apart. Using a hacksaw blade, I
cut the secondary turns and drove them out of the core with a punch.
Next, I used teflon tape around the core for insulation, and wound the heavy
thermaleze insulated wire though the windows in the core to complete my low
voltage winding.

Really...! Hmm... perhaps time to re-visit the "WWVB receiver using op-amps and a small microcontroller" ida? One of the regular contributors to Circuit Cellar Ink tried it a while back (4 years?), but wasn't successful. A successful project would be worth a write-up in some hobbyist magazine (of what's left... Nuts & Volts seems to be about it in the US...)

Anyone know which time service folks in Oz or the Kiwis use?

Yes, I've seen Jim's design before; it's quite impressive for 1974! For a
contemporary design, the idea is that you could get by with far fewer parts
(if not fewer transistors -- they're just buried in the ICs!).

Speaking of diodes...

Is there any reason you can't use the so-called "zero Vf" microwave Schottky diodes for a crystal radio for the AM broadcast band? Is it just expense that keeps people (in a hobbyist capacity) from using them?

To be fair you'd have to do it with components that were available at reasonable prices in that era. My 2nd DCF receiver was built with several AF126 germanium transistors. On the first one I cheated by using opamps and somehow that didn't feel right back then.

Except for the fact that one receiver drove a Nixie display I never built one with tubes. Now wouldn't that be something?

Yes, but if these crystals are the only thing you'd have to buy right
now that would easily become $10 with S&H. Or about half of what an
atomic clock is at the discounters and there the price includes a huge
display along with the receiver parts.

Hello. I have a small "touch lamp" - you touch it anywhere, it turns on, off, or dim. I know that it emits some minor RFI which can effect nearby radios.

The table is small, so the touchlamp is right next to one of my mini-system speakers. (speaker = 100watts max, "medium" size). The lamp metal is about 4 inches from the main speaker cone magnet.

Is this safe? Can this damage the speaker, or wreak havoc with the speaker magnet? Can it effect the speaker when it's "on"? Or will a touch-lamp's circuitry have no effect on a speaker?

Thank you for any advice...

Hello Michael,

> Maybe use them with the 60.000 KHz crystals to build a very narrow
> crystal filter?

Maybe but most WWVB receivers are more crude. They aren't concerned about shape factors and stuff, all they want is enough selectivity to make sure the things sync at night even if in California or Arizona. So there is usally one crystal as a filter, or two in series for the better ones.

The worst problem is idle current, 1.2-1.5A on 240VAC, so you should
use the extra space and add 100turns for the primary, and reduce the
idle current to 0.3A. This will also reduce the output voltage below
2kV DC. Many cores are standard E120 types and it isn't worth the
trouble of trying to use the original rubbish

I've planned to bring some information on
http://home.online.no/~la8ak/d4.htm , but haven't translated it into
English yet

Oh, I'm all for cannibalizing the commercial clocks, what with their pretuned ferrite loops, 60kHz receiver and demodulator, as a cost-and-time-effective method. But if someone did want to roll their own...

I have custom ordered tuning-fork style crystals down to 12kHz, and they were way more than the mass-produced $1 jobbies! I think $30-$50 each in onesies. $1 is really cheap in comparison.

Tim.

In the shape of a mantle clock it would work. Open chassis, of course,
so the discerning visitor can admire. With nixies it would look really cool.

In that case I'd probably try to do it with a PLL stabilized
Q-multiplier instead of a crystal filter. Should work just fine at
60kHz. Or a conversion scheme that puts the IF in the low kHz range
where it can be done with active or switched capacitor filters. Still
have to stabilize the oscillator though. Just as a proof of concept...

True, $1 is cheap. Custom crystals are less and less popular. Some of
the companies I used way back when are no longer there or aren't doing
it anymore unless you buy thousands.

You were making "galena" which is PbS, Lead Sulfide. I used one for my first crystal radio in the 50's. Had to find a sensitive spot. You might be able to find some in a hobby shop (If you can find one.) that deals with minerals.

You might also try a "blue blade" razor blade. The GIs used them in WWII for making foxhole radios. The bluing produced a chemical (unknown to me) that rectified the signal.

For this purpose, almost any anodized metal should suffice. The "Blue
Blades" were, AFAIK, simply anodized and polished high-carbon steel.
The aonodized surface would be covered with fine steel-oxide crystals.
I wonder if anodized aluminium would work? I'm theorizing here that we
want some sort of crystal to interact with a base conductor.

This kind of thing is still done for some special "blue" hack- and
reciprocating saw blades. I think there are even circular saw blades
that are anodized in a similar way. These would be expensive and hard
to come by. I'm sure people will pay to get them rebuilt rather than
toss them out, and I have no idea how an average tinkerer might easily
cut pieces of a think saw blade up!

However, if you can find a hacksaw blade treated in the same manner,
this give supplies for a number of experiments.

Micrometer.
Vernier caliper may also work.
Either under $30US.

A cautionary note - if it's that critical, then re-using wire which
has alread been wound might not be the best idea. You'd be starting
with wire which had already been bent/flexed, and if you aren't
careful this might put some kinks or irregularities in the winding of
your new coil which might affect its impedance or Q.

You might be able to do it with a vernier caliper.

24 gauge has a diameter of .511 mm or .0020"

30 gauge has a diameter of .255 mm or .001"

Every 3 gauge numbers corresponds to a 2:1 ratio in wire area (amount
of copper). Every 6 gauge numbers corresponds to a 2:1 ratio in wire
diameter.

Two quick options:

Many kinds of wire have information printed on the insulation.

There are many tables which give the diameter, so machinists verniers
or a mike would do.

Or you could collect a set of samples of known wires and compare. Note
that solid and stranded are a little bit different.

Recycling solid wire from other coils might leave kinks or weak areas
where it was bent before. Insulation integrity matters, too.

Get a nice piece of smooth round rod and tightly wind a little over a lineal inch of wire closely spaced as possible. Count the turns in one inch and divide the number of turns into one inch and you'll have a very good measurement without any cost.

> Does anyone know how to measure or determine the wire size.

If I need to check, I use a vernier caliper to determine the diameter of the strands (2*r)and then calculate the total cross-sectional area as (pi*r^2) * number of strands.

This gives a result in mm^2. Which is the standard measure in most of the world.

To do the same you'll need a chart to convert from cross-sectional area to AWG. Google will find you one.

Ooops, you're low by a factor of 10:1 in the inch calculations. Just
as well, since a caliper is hardly repeatable to 1 thou, let alone
measuring a diameter of that size with any accuracy.

Yup, I added a zero in there. 24 gauge is 20 mils (.02"), 30 gauge is
half that.

Works out to 50 or 100 turns per inch, close-wound, and the suggestion
to use that method was probably the best and cheapest I've heard.

BM> How does using a solar cell prevent a detector diode from getting
BM> zapped?

By mounting the detector diode under the solar cell of course! That
wasn't my point however. What I really meant to get at is that high
impedance headphones (25K ohms) are hard to find these days as are
germanium anything. The better alternative is perhaps the Schottky
small signal diodes and a crystal earphone (which are also rare). On
the other hand if one powers a small transistor radio from a solar
cell charging a battery then it results in something practical.
Perhaps it isn't as educational as winding your own coil on a
cardboard tube of Quaker Oats and finding a Galena out in the
old quarry but there is nothing wrong with not re-inventing the wheel.
Do we really need to re-invent it to learn how to be a car mechanic?
We would have to be idiots if that was the case.

Al> either.

A practical answer: measure the resistance of a known length of wire.
You don't need a milli-ohmmeter to do this. Simply inject an accurate
current into a known length of wire, let's say for example 1 ampere.
Then use a dmm on the 200mv range to measure the voltage drop. This
gives a direct reading of milliohms x feet. Multiply this value up to
a range of 1,000 ft and look it up on a standard wire table and read
the gauge column. That's it! No fussing with diameters or micrometers,
microscopes or conductivity. One note of caution: if the wire glows,
the current is too large!

>Does anyone know how to measure or determine the wire size.

Use a micrometer or a vernier slide gauge to measure the diameter. Assuming that your wire is enamelled, 24 AWG is 0.022 inch (maybe +/- 0.002) diameter and 30 AWG is 0.011 inch diameter.

==========
As an alternative to the above you might consider a piece of 'air-spaced'
coax (10 mm OD) as used for sat TV ,say 100 mm long ,connecting the centre
conductor to the sensor's in- & output connectors, earthing 1 side of screen
only.
By inserting a (possibly teflon) insulated wire through one of the 'air
gaps' you create a suitable pick-off for forward/reflected power (SWR)
measurement. The 75 Ohms impedance of the short piece of coax is of no
concern in a 50 Ohms environment.

==========
A suitable enclosure could be made from double sided printed circuit board material , available from the surplus trade or at Hamfests.
The 'lid' supposedly of identical size as bottom could be fitted by means of screws having their nuts soldered into 4 upper inside corners. For the above enclosure you would need 2 pieces 10"x10" and 4 pcs 7"x10" .
PCB material can be easily trimmed to size and subsequently soldered. The final enclosure could be polished and subsequently varnished if appearance remains important.

==========
Some time ago I was given an enclosure for an outdoor surveillance TV camera which had a suitable heater (50 Watts resistor) switched by a bi-metallic temperature switch. A homebrew solution would be an opamp circuit with 2 diode type temperature sensors,measuring in-and outside temperature ,maintaining an inside temperature approx 2degr C higher than the outside temp.
This would be adequate to prevent condensation .
Seems a bit overdone at a first glance ,but would ensure protection of valuable RF equipment.

Perhaps someone involved with Mobile Phone Cell Systems outdoor equipment would care to comment.

Hi Albert,
What is the upper freq limit on this chip? I am always looking for a good AM
dtector. 9MHz is current interest.

Thanks,
BTW, if you are the same fellow asking about wire gauge- a
micrometer/calipers is by far the more accurate method. The gauges just do
not work well for small diameters. And, you'll find lots of other uses for
the calipers.

73,
Dale

Is there any reason to suppose it contains a coupling capacitor or
something that would limit the low-frequency response? It seems rather
unlikely. But the definitive test invokes a little-used technique in
these days of calculations and simulations. It's known as 'trying it'.
(;-)

It isn't as if testing at 20 kHz is rocket science, after all.

Since this is a superhet chip (IIRC), the problem is more likely one of LO
bleed through into the IF. The LO frequency would have to be on the
high side of the receive frequency, so in this case, with a 455Khz IF,
the LO would be at 475Khz. The LO signal bleeding through the IF filter
would probably be as strong, or stronger than the 20KHz signal you were
intending on receiving.

At some (very) low frequencies the 1/f noise will make the stated
noise figure invalid :-).

Some microwave bipolar transistors will have a quite bad noise
performance at HF (and some even VHF) frequencies due to the 1/f
noise, but since the maximum frequency for that AM radio is not very
high, I very much doubt this would be an issue at 20 kHz.

After all, the environment noise is quite high at these frequencies,
so unless the antenna is very lossy, the receiver noise figure is of
very little interest anyway.

The articles I've seen for it (and it's basically the old ZN414), the top
of the AM broadcast band or a bit higher.

But it's meant for simple receivers. You have a single tuned circuit
at the front, and then "selectivity" comes from good AGC action. It
may run out because the selectivity is unsuitable at higher frequencies,
and not because the IC can't handle them.

Ahhh! Well, that changes everything. I took a look for the spec sheet, and found the sheet for the ZN414Z, which is apparently almost identical to the MK484. There are two things that I think would limit operation at lower frequencies:

1) the gain appears to be purposefully rolled off at about 40KHz. That is to say, it approaches zero at that frequency.

2) the detected audio stage has bandwidth out to 20KHz.

Imagine what would happen if you had a signal with a 20KHz carrier frequency. The carrier frequency would pass right through the detector and into the audio channel. The AGC, which appears to be audio derived, would get seriously upset, and if the 20KHz signal was modulated, you create some very interesting hetrodynes.

That being the case, it appears that the manufacturer tried to keep the operating frequency far enough away from the audio passband that a simple filter would suffice to prevent interferrence.

It probably won't work well at all as a 20KHz receiver.

Yes, having found a 'data sheet' (handwritten), I see it has four
coupling capacitors between the stages. Not good news.
>
>2) the detected audio stage has bandwidth out to 20KHz.

That may be controllable, but it's beside the point of there is no
useful gain at 20 kHz. In that case, a 741 would be usable, but a 709
would be better (small signals). (;-)

>>
>> Any suggestions?

A non-destructive measurement is best. Along about
1946 my middle school (we called it "junior high" back
then) electric shop instructor demonstrated how to use
a mechanical caliper and how NOT to squeeze too hard in
doing so. Soft-drawn copper common to wire is fairly
easy to squash when using a caliper. Using one requires
a VERY light touch on the wire, just enough to be able
to pull it slightly through the caliper jaws. Even so,
pulling on soft-drawn copper wire is going to distort it

slightly so the measurement is going to be on the small side. Snipping off ten or twenty short lengths, then measuring the total width and dividing by the number of lengths will be a bit better in accuracy.

A pocket optical comparator is handy for this and other uses, especially when trying to get a measurement on something already mounted with epoxy, varnish, etc. as in windings of electric motors. While the "100-foot resistance test" is a practical idea with a roll of wire, it is hard to do when the wire comes from a motor or transformer giving its all to the project.

As a practical matter, the wire size in small (such as HF range) coils won't matter much on either the inductance or Q tolerance. For example, Dropping from 30 AWG to 32 AWG isn't going to be a disaster in cylindrical ("solenoidal") or toroidal forms. The change in inductance will be aligned-out on trimming in the circuit itself. Q is going to change much more depending on the material of the coil former and the presence of nearby conductive objects such as shields.

If a Twenty is too much for a pound or so of new wire stock, then nobody can afford a Q Meter or inductance meter to do an accurate measurement. Get with some friends/acquaintences and share the cost of new stock.

Just some practical thoughts after doing a bit of winding in my time...

1917. The Season for needing Surge Protectors and Interference Filters is upon us.

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-04-08 19:19:50 UTC
From: American Technical Resources <knolla@american-technical-resources.com>
Message-ID: <1112987990.944545.162210@o13g2000cwo.googlegroups.com>
Source record: 19449

The season for needing Surge Protectors and Interference Filters is upon us, purchase them before you need them, for peace of mind, protection and savings. We carry a wide array of surge protectors for all voltage requirements and signal interference conditions. Suggest to your friends and customers that "Surge protection doesn't cost......It Pays." Be prepared for your requirements and that of your customers. We can produce OEM quantities and look forward to your inquiries at www.American-Technical-Resources.com

Remember that Telephone and cable lines can also conduct high voltage -- for full protection, you should also guard against surges from your telephone or cable lines. Any lines carrying signals into your home can also carry a power surge, due to lightning or a number of other factors. If your computer is connected to the phone lines via a modem, you should get a surge protector that has a phone-line input jack. If you have a coaxial cable line hooked up to expensive equipment, consider a cable surge protector. Surges on these lines can do just as much damage as surges over power lines.

"DO your best to secure ground, this is always the foundation of good surge protection"

Allen Knoll

Technology Applications Engineer

American Technical Resources

8 Stark Road

Worcester, Massachusetts 01602

Correction: the rating was increased about Jan 28/2005, not 2004, correcting an obvious mistake. This longstanding, unsubstantiated 1H rating on DXing.com probably adversely affected the opinions of some uninformed individuals.

They sure do, Frank! I sent the webmaster a message complimenting him on his work with the comment that the one thing missing was credit to the inventors of the mods, "from the pioneering Frank Cathell to whoever had developed these new ones I had never seen before". I have no idea who is behind the site and whether it's motivated by anything other than enthusiasm to share what he/she has done. It's first class, all the way.

Actually, I do it regularly with .15mm wire (I don't know the guage)
Of course, you have to be able to set the blowtorch so that it's producing
a yellow flame that's not too hot, a lighter works well.

IIRC there's something called Formvar that will self-strip upon
application of a tinned iron.

There's also the chemical stripping agents.

Source record: 19458

The season for needing Surge Protectors and Interference Filters is upon us, purchase them before you need them, for peace of mind, protection and savings. We carry a wide array of surge protectors for all voltage requirements and signal interference conditions. Suggest to your friends and customers that "Surge protection doesn't cost......It Pays." Be prepared for your requirements and that of your customers.

Remember that Telephone and cable lines can also conduct high voltage -- for full protection, you should also guard against surges from your telephone or cable lines. Any lines carrying signals into your home can also carry a power surge, due to lightning or a number of other factors. If your computer is connected to the phone lines via a modem, you should get a surge protector that has a phone-line input jack. If you have a coaxial cable line hooked up to expensive equipment, consider a cable surge protector. Surges on these lines can do just as much damage as surges over power lines.

"DO your best to secure ground, this is always the foundation of good surge protection"

Oh, that's cheating. (;-) When you write 'blowtorch', you should mean
'blowtorch', 1000 C plus.

The almost cool flame of an alcohol burner is good, especially as it has
a large part of its volume that is chemically reducing.

>IIRC there's something called Formvar that will self-strip upon
>application of a tinned iron.

Once upon a time, there was 'flux-enamelled' magnet wire, which was
really easy to solder, but the coating was fragile. Then there was
'solderable', which required an iron temperature substantially higher
than for normal soldering. But that gave off toluene diisocyanate, which
is poisonous if you breathe it for 20 years, so you had to use it under
extraction, and that made it fall out of favour.

Not according to DXing.com who gave it 3: " A rating of 1 to 5 stars for the
model as a value on the used market.
HHHHH Excellent HHHH Very Good HHH Good HH Fair H Poor. "

That Panasonic RF-4900 you sold for €85.90 is rated by the same folks at 2
(HH) - that's closer to crap, but still 'Fair'. On Mar 30, you posted that
you wanted to swap it for a DX-394
http://groups.google.ca/groups?q=rogers.mail%40ntlworld.com&start=10&hl=en&lr=&selm=hZz2e.826%24wQ2.632%40newsfe5-gui.ntli.net&rnum=12 .
Sounds like an upgrade from a 'Fair' to a 'Good' value radio and
inconsistent with your expressed opinion.

The Kenwood R-2000 you were selling off in 2003 is rated at 4 (HHHH) by
DXing.com. That's 1H more than the DX-394 and it sells for 2-3 times the
price on the used market. Just a little less crappy, was it? ;-)

> would probably be as strong, or stronger than the 20KHz signal you
were
> intending on receiving.

Two reasons for using an IF amp are to amplify a fixed freq even as the
receiver is tunes, and to amplify a lower freq so that the bandwidth is
narrower. But since neither of these is necessary, it makes less sense
to upconvert to 455kHz, or to use 455kHz as the IF.

So it seems more logical to reduce the IF amps to the receiving freq, by
padding the IF tuned circuit caps. There is one barrier though: you
can't pad a 455kHz ceramic filter.

As I understand it: NiMH batteries do "prefer" a somewhat different
charging regime than NiCd batteries - they're less tolerant of being
overcharged.

A NiCd "smart" charger will usually charge the batteries with a
constant current, and monitor the voltage across the battery. When
the batteries hit full charge, they begin to heat up, and the voltage
across them decreases somewhat. The charger will detect the voltage
drop (a "negative delta V") and shut off the charge. Fast chargers
usually include a temperature sensor, as well, and a failsafe timer.

NiMH batteries can be charged with a similar regime, but it's
apparently not a good idea to wait until the delta-V goes negative...
by that point the NiMH battery has heated up quite a bit, and that's
not good for its lifetime. A NiMH smart charger will cut off the
charge current when the voltage across the battery stops rising ("zero
delta V"), before the battery heats up very much.

NiCd batteries can be trickle-charged at a low rate, and I believe
I've read that this is not a good approach to use for NiMH batteries
(or, if you do it, the trickle current must be a good deal lower).

See if you can find the data sheet for the Maxim MAX712 and MAX713
charge controller chips - they have a lot of the details.

'cause crystal radios are more fun, and when your 10-year-old puts one
together he or she can understand each and every part in it (those
charge regulator IC's are kinda hard to grok when you're not firm on how
a diode works).

A word from Robert Heinlein's 1961 novel "Stranger in a Strange Land".
Rough meaning is to understand thoroughly and profoundly.

"As one character from Heinlein's novel says:

'Grok' means to understand so thoroughly that the observer becomes
a part of the observed - to merge, blend, intermarry, lose identity in
group experience. It means almost everything that we mean by religion,
philosophy, and science - and it means as little to us (because we are
from Earth) as color means to a blind man. "

I use either a dial calipers or a micrometer. But then the insulation
can make it sizeably larger than the value given in the wire tables.
The wire tables have a column which gives 'ohms per 1000 ft' which is
just another way of saying milliohms per foot. So if you measure ten
feet of 30 AWG it should measure 1.04 ohms. My cheap meter test leads
are something like .4 ohms, so it's really difficult to get any accuracy
at that low a resistance. I have a Leeds Northrup wheatstone bridge,
and it's not very good either at that low a resistance. So I put the
wire or whatever on a power supply and crank up the current to a quarter
amp, and then measure the V drop and calculate the resistance from that.

I don't believe anyone uses vernier calipers anymore. I've got a Helios
dial caliper made a long time ago in Deutschland, but nowadays a caliper
with a LCD is probably a lot cheaper.

I do, got fed up with resetting the mechanical dial type through the rack and pinion becoming dirty, and electronics/robustness issues with electronic types.

>Helios dial caliper made a long time ago in Deutschland, but nowadays a
>caliper with a LCD is probably a lot cheaper.

In UK, you can get vernier calipers for around GBP1 (and mine check out as quite sufficiently accurate). LCD calipers are about GBP35.

I use that trick too. The only sensible way to measure a coil's winding R.

Graham

Ohhh... I assumed anyone serious would be using a Mitotuyo ? digital LCD
vernier caliper anyway. We certainly have one.

You can get low-end LCD calipers in the US for the equivalent of about
GPB8 plus tax. For GPB1 (<$1.99) I think you'd get some stamped or
plastic item that would only be good to 0.01".

No, they are metal, and claim to measure to 0.001 inch, 0.02 mm. I've
checked mine against a good micrometer and it's as accurate as I can
read the vernier. YCCMV, of course.

Hi All,

I'm about to build a 4CX1500B amplifier for 2m.

Most, if not all, descriptions are blowing air into the enclosure on the base side of the tube and the air goes through the socket and finaly through the anode chimney.
For several reasons i would like to blow into the anode enclosure directly onto the anode, the air would then go out through the anode chimney. Only a small part of the air would cool the base of the tube through small holes in the anode/cathode separation.

Is that a stupid idea ? Is there any reason not doing so ?

>
>No longer there.

The link was too long and got broken.

Much better to enclose all links in <> brackets, which will still work
right even if split/word-wrapped into multiple lines. Works with all
of the browsers I have used.

For example:
<http://cgi.ebay.com/ws/eBayISAPI.dll?ViewItem&category=20766&item=4369843430&rd=1>
for the item above, which works as Watson intended.

There are also options like tinyurl, but some do not trust that.

Happy trails,
Gary (net.yogi.bear)

Long as it doesn't start glowing red. ;-)

Probably not such a good idea for measuring the series R of inductors.
Unless you run a Hi Power tape demagnetizer over it when you're done..

BTW, speaking of tapes.. I read that the company that made Irish and
Ampex tape has closed. Looks like everyone has been going to CD-Rs.

Zackly. The ones I've seen in stores don't go down to a thousandth.
Not to mention the jaws probably wear and/or get dimpled by the sharp
edges of objects, ruining the accuracy.

But at two bucks apiece, you just treat them as disposable and discard
them at the end of the day. ;-)

Unless, of course, you're a plastic surgeon using them to measure the
results of your liposuction machine. ;-))

Bumfuzzles me why you'd want to cut it up into a bunch of hard-to-handle
strands. Just wind it around a dowel as someone else suggested.

Patrick -

I would suggest that you look at the 6M DXpedition Amplifier designed by
Chris, G3WOS.
Great photographs and commentary on desire to stay portable, cooling
requirements and
overall compartment design of the amplifier. It may give you a few ideas.
He used a Eimac 3CX1500A7 (8877) tube.
http://www.gare.co.uk/amplifier/

For your tetrode 4CX1500B amplifier, I would strongly suggest using Ian
White's (G3SEK) control board:
http://www.ifwtech.co.uk/g3sek/boards/tetrode/tetrode-1.htm

Ian also has his 1997 QEX article available for reading on tetrode designs:
http://www.ifwtech.co.uk/g3sek/boards/tetrode/tetrode-3.htm

> 73, Patrick

No, not a stupid idea at all. That's the way I do it on my current
4CX800 2m amp, and I have used that method on several 4cx250 class amps
in previous years. I think its was popularized, if not initiated, by
K2RIW some decades ago in his classic 432 amp.
Three things to watch for:
1) make sure there is a good seal from the outer part of the plate
resonator to the outside world; I use 25mil teflon sheet as a chimney
with clamps made from brass strip.
2) ensure there is an exit in the grid compartment so that the air can
flow through adequately.
3) put some mesh on the blower inlet to the plate cavity, otherwise the
resonance will be affected by the fan rotation. Gives a subtle, but
noticeable AM buzz.

Good luck with the project.

I do.

I haven't got a LCD one, but a magazine sends me one every year.
Ok, it's made of plastic, but it works fine, and is accurate enough for
me, seeming to be within about .05mm

I'd like an LCD one of course.

Not sure if this matters but on the larger tubes, the cool air was needed to keep the tube contacts from heating. Also, there was an issue with heat buildup on the base of the tube due to the filaments.

The tubes I am talking about were the 3cx15k and larger in a broadcast environment so this could be moot.

Hi Al,

OK, thanks for the ideas. My first guess was that i will have difficulties to find a blower that can give me enough pressure !

I think that there will be less back pressure than blowing all the air through the socket...

I want to maximize the RF shielding between anode and cathode, by leaving the smallest space possible in the socket. Doing this, the air would have some difficulties to travel through... I could also drill some holes at the other end of the cabinet, but that would reduce the useful air flow also !

I will have a look on K2RIW's amps. Tnx for the info.

btw, i want to make my amp as small and simple as possible.. I will use a cathode driven design with G2 grounded and plate resonator made by a simple 1 turn coil, no line, no PFTE, etc ... (seen on YU1AW's "lazy builder" page)

My actual concern is to find a simple but stable way to make a 10 pF HV variable cap. Berylium copper and/or vacuum caps are not common here on Corsica ! hi hi

You should shell out the $20 or whatever then (or $100 and get a
Mitutoyo or other brand name with a bit better "feel"). I use mine all
the time- for rough (0.001") width, diameter, inside diameter
(rougher) and depth measurements. A micrometer is useful for precision
measurements, but less necessary for an EE.

Best regards,
Spehro Pefhany

Unfortunately, $20 is quite a lot of money at the moment :/

I don't have any real need for it - I've got a 0-25mm micrometer, and
the plastic caliper fills in for the rest.

I don't have any tools that can maintain that sort of tollerance anyway,
so my need is less.

You don't have a file? ;-) Just double-checking lead pitch etc. is
worth a lot by times.

True.
I don't really have that much that I need to hold accurate tollerances
for anyway.

The file is a much underestimated metalworking tool.

No tears here about that demise. I haven't used Ampex tape since 1969, in Korea. We switched our three 12-track recorders to 3M tape because Ampex sandpapered the heads.

This old war horse finally went CD-R and CD-RW about a year ago. CD-RW is wonderful for PC HD backup. Can't bear to let go of my Teac 4010-SL r/r deck though. I bought it in Thailand in '71, used it until '81 or so, and then packed it in its original box. It's been used twice since then. Every once in a while I pull it out to show to some kid as an antique. :-)

There is an IEC standard, IEC 60317-0-1, which specifies a range of
metric diameters for enamelled copper winding wires.

A ham friend told me that he heard that DSPs really work at least a little bit. He doesn't have one and neither do I (although many of the newer and more expensive rigs have them, and there are one or two outboard DSPs that are available that can be added to older rigs in some ways). I don't know all that they can do (auto null heterodynes? auto noise reduction [what kind of noise reduction?]? audio enhancement [or audio bandpass shaping] of some kind?) but if static crashes can be really removed or attenuated, that would be of use to me. Auto null of heterodynes would be nice on those occassions when tuner-uppers decide to tune up on my frequency in which I am already in two way contact with others (on ssb phone). And, maybe there are some other useful characteristics I don't know about. But, are these really effective? For example, a 20 db heterodyne null is not much. Nulls have to be about 50-60 db to be useful.

I'll take any kind of comments, suggestions, refernces to testing, or personal experience, pro & con recomendations, ...anything...

There are some good demos at
http://www.radio.bhinstrumentation.co.uk/html/demonstration.html . I have a
cheap Radio Shack DSP40 that performs at the lower end of the scale as far
as these go. It does a remarkable job of multiple heterodyne reduction and
selectable audio passband but its noise blanker is next to useless and it
does not do noise reduction other than through selectivity.

The performance of a DSP is very dependant on the software it runs
under.

If they didn't work, none of the current military radio systems would be any use - they all use DSP! I've designed an audio processing DSP system using one of the new dsPIC devices and a codec - just two small chips. The codec includes a mic pre-amp and headphone amp.

I've not had a lot of opportunity to use DSP for Amateur
applications, however I have used it in the Icom IC-718 for Civil Air
Patrol applications.

Several of CAP's 4mHz frequencies suffer from foreign hetrodynes
and other ectopics. The DSP has been over 90% effective in making the
channel "usable".

This coming Sunday.... The seasons first....

+++ Now even more Buyers Parking !!!
Thanks to TKT we have use of their new parking lot
across Albany St from the SWAPFEST !!!

!! ** More Buyers PARKING is available ** for details see
http://web.mit.edu/w1gsl/Public/flyer

*** !!!! In our Traditional GARAGE and the adjacent lot !!!! ****
so come rain or shine or super heat the Flea is on !!!

********* $1 buyers discount with hardcopy of this notice ********

COMPUTERS - ELECTRONICS - HAM RADIO - COMPUTERS - ELECTRONICS - HAM RADIO

FLEA all SUMMER at MIT
Sunday April 17th 2005
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take
place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >2000 cars!

Buyers admission is $5 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $20 for the first and
$15 for each additional at the gate.

The flea will be held at the corner of Albany and
Main streets in Cambridge; right in the Kendall
Square area from 9AM to 2PM, with sellers set-up
time starting at 7AM.

SEASON PASS + Advance Seller Discount

A sellers discount season pass is available which
offers a 30% discount. By prepaying you get a
discount and earlier admission. See the registration form.

*** Attention Sellers ***
Prepaid vendors.. Season Pass or monthly,

will be admitted FIRST.
Separate lines will form prior to gate opening
for prepaid and nonprepaid vendors

!! RAIN or SHINE !! Have no fear of rain, a covered
well illuminated tailgate area is available for all
sellers (6'8" clearance).

Talk-in: 145.23- (PL 88.5) W1BOS/R and
W1XM/R-449.725/444.725 (PL 114.8/2A).

Of course they work. How well, as Michael points out, depends on the
software.

> are available that can be added to older rigs in some ways). I don't know
> all that they can do (auto null heterodynes? auto noise reduction [what

DSPs can be programmed to do almost anything, but in amateur radios, they
generally are used to reduce noise and null hetrodynes.

> of some kind?) but if static crashes can be really removed or attenuated,

In general, the point of DSPs tends not to be to remove static crashes.
Some of the newer noise blankers are, in fact, processors that might be hard
to distinguish from DSPs. They tend to do a very good job on pulse noise,
but I haven't tripped across any that are even decent on static crashes.

> really effective? For example, a 20 db heterodyne null is not much. Nulls
> have to be about 50-60 db to be useful.

Remember, these things are software rather than filters. The stronger the
heterodyne, the easier it is for the software to recognize it.
Unfortunately, it's not magic. A really strong heterodyne is going to be
driving your AGC and perhaps overloading some amps in your chain, so it
isn't like it magically disappears with no other effect. Still, very often
the DSP can make life more pleasant in the presence of lids.

To distingush it from a micrometer caliper at one end of the tool
spectrum, and a monkey wrench at the other. ;-)

Cheers!

1989. FS. TOWER_MOTOR_ROTOR_FOLD_OVER_SELF_SUPPORTING

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-04-12 00:35:12 UTC
From: ME <aeschelon@hotmail.com>
Message-ID: <sg5m5116s6d85fh49rph2hti8sp4irpbof@4ax.com>
Source record: 19420
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.amateur.misc

It is with great misgivings that I am about to sell my
precious tower.

I am moving and also getting older and not going to put up
the tower at he new location.

I have a Telex 55 foot, fold-over, MOTORIZED,
self-supporting tower that is in excellent shape. This is a
SERIOUSLY HEAVY-DUTY TOWER.

This has a commercially built rotor control box that
controls a prop pitch motor that would turn a tank. The
prop-pitch motor is included and already mounted. For a few
bucks more, I will include the t-6061 mast and even a
fiberglass cross-mast.

This jewel is in my backyard and is currently up.

After I take it down, it will be ready to put up and get on
the air. I have everything with it including the in-shack
control box (HAM_M).

I NEED TO DETERMINE if anyone is seriously interested in
this because I have other things that I need to do rather
than take down a tower that there is not a serious prospect
for.

The tower is in Houston, Texas but is well worth a drive to
Texas

I am expecting to offer this for around $2500.00 FIRM.

Thanks

Noise blankers tend to work best if the noise gate is derived from a
broadband signal, separate to the wanted signal. No amount of DSP magic
will help if the signal is already bandlimited
The Linrad page at http://www.nitehawk.com/sm5bsz/linuxdsp/linrad.htm

discusses this in detail.

In-band noise blankers can do a pretty good job at lower cost and less complexity if they are designed properly. The book "HF Radio Systems and Circuits" from Noble Publishing, also available from ARRL as item 7253, has some material and references on this subject.

Isn't the effectiveness of DSP critically dependent upon the A/D converter;
its dynamic range, it's number of bits and it's sampling speed?

Re: Peter's comment below; I don't know enough about DSPs to answer. I got a few ideas and notions from all that responded. Me? I was most interested to learn whether any DSPs could do noise reduction of any kind. Heterodyne from lid tuner-uppers would be nice, too, and so would passband width and position.

I did google "DSP & ham radio" and quite a bit came up and it will take me some time to check out enough to figure out if it might be worth chucking out $200+ on a decent outboard unit (I can't justify laying out a big chunk of money on a really modern xcvr with built in DSP just for those relatively rare moments when I have pulse noise, hash noise, or a heterodyne, or someone with spillover from an adjacent frequency), so I need something that works pretty good. One guy said there is no "magic" meaning to me that maybe I should not expect rabbits to come out of hats easily and quickly. My friend with whom I have weekly ragchew ssb QSOs told me that just putting on headphones helped him read me when I was weak and his noise level was high. Also, it helped him a lot when I bought a linear and went from barefoot to four 811As. But, if a nearby QSO starts and thier audio is broad, the spillover can be annoying if they are stronger. Thus, if I could "DSP" a narrower passband and shift the frequency (or at least shift the "knee"), that might be useful.

Regarding efficacy, I remember back some 3-4 decades ago they were coming out with audio compandors that "compressed" 2.5+ khz of audio bandwidth into a signal about 1.2 khz wide, thus saving bandwidth but the gadgets never caught on bigtime and some gossip said that the extra "audio punch" and thus power boost (3 db-ish) really didn't end up doing that much. So, that is one example of a fancy-schmantzy gadget that didn't last long. This new PSK-31 audio jazz is also out there (the box is about $500 ?) and you need one at both ends of the voice QSO and I have not yet heard many of them (the review said that if the signal drops too low, the voice info just stops coming through the speaker, so it has its caveats, too).

Again, thanks to all those who made comments.

I just purchased a tilt-over mast that I'd like to erect:

The base section begins with a 16"-square piece of 1/2" steel with four holes on 12" centers and is welded (with four pieces of steel, sorta like rocket fins) to a pipe which rises 17.5' to the pivot point. The tilting part extends 16' further. All of the above pipe is 2 3/8" in diameter, but a smaller-diameter pipe (for mounting a rotor?) sticks out the top end of the tilting section another foot or two.

Can someone suggest how big a blob of concrete and how much rebar I'll need at the bottom to erect this mast to be freestanding?

Contact the manufacturer of the tower and see what they recommend. My U.S. Tower is 55 feet high and required a slab 5 feet by 5 feet, steel reinforced and 6 feet deep. This is quite a blob of concrete and the type of concrete is important also. My son is a civil engineer and I did what he recommended.

Depends. Some tapes (reportedly mostly from the 1970s) disintegrate. A
couple of years ago I had no trouble playing my tapes from the late 1960s,
but...

I'd attempt to hawk em on ebay before tossing them. Maybe somebody can
do something with them regardless of condition or relevance of code
practice. It doesn't make sense to just cart them to the dump without
trying.

I have a Triex W-51 Crankup in my yard. Collapsed it is about 22 feet high and extended it is 51 feet. The manufacturers recommendation for the "blob" of concrete is 3 feet by 3 feet by 5 feet deep, roughly. This is about 1.5 Cubic Yards of concrete. I don't have the specs handy, but I believe the rebar mount extended about 3 feet down and was centered so that it is at least 6 inches from any side. To make sure that everything sits where it is suppose to, and will be plumb when erected, the rebar mount was bolted to a 2" x 6" wooden form, leveled properly, and then the concrete was poured around it.

There is a reflector around called something like "Tower Talk" that would be able to give you more details and advice. However, I don't remember the link. Maybe someone else can supply it.

It's a fairly big job and takes a bit of planning.

>Yes, and the AGC system that makes maximum use of the A/D and D/A range.
>See for example the organization of the Ten Tec Orion.

If the DSP system really needs some kind of AGC, then it is a useless
toy :-).

If you have a strong and a weak signal in the ADC input bandwidth and
the system gain depends on the strong signal, then the weak signal is
going to be drowned into the (quantisation)noise whenever the
amplitude of the strong signal is increased.

Any properly working DSP system should be designed in a way that it is
capable of properly converting the thermal noise as well as the
combination of all strong signals in the input.

The only justification for using AGC in front of a DSP system is that
if antennas with dramatically different efficiencies are used. For
instance, if the receiver input is switched between a full sized
dipole on 160 m and a ferrite rod (with perhaps -40 dB gain), then it
is quite acceptable to modify the gain with some kind of AGC, but this
could be handled as well with some antenna specific gain presets.

If the system is working an hour on a specific band with a specific
antenna, you should not need any kind of AGC depending on the actual
signal level. If you need AGC for this, then you are going to have
problems, if you are trying to receive any weak signal close to a
strong signal.

What one really needs are ADCs with many bits, say 24 bits,
sampled at least twice the highest signal frequency to be digitized.
One has to avoid saturation (overflow) else the rest of the
signal gets blanked during the overflows.

The LSB should be less than the band or thermal noise in the _input_
bandwidth, so that it would act as dithering noise. For terrestrial
VHF/UHF/SHF systems, the antenna temperature is close to 300 K and
thus a noise density of -174 dBm/Hz. Assuming 10 kHz ADC input
bandwidth, the equivalent noise power would be -134 dBm. In order to
be able to correctly convert a strong signal _and_ the broad band
noise riding on it correctly, the maximum signal level at the antenna
for 16, 20 and 24 bits would be -38 dBm, -14 dBm resp. +10 dBm or
assuming 50 ohm antenna impedance 2.7 mV, 44 mV resp. 710 mV. Not
very common values on VHF/UHF.

At HF, the band noise is typically at least 20 dB stronger, so the
gain in front of the ADC can be reduced and thus the maximum antenna
voltage would be at least 10 times larger, so even the 16 bit
converter would tolerate a single S9+55 dB signal.

However, in order to be able recover weak narrow band that would be
buried in the 10 kHz broadband noise, quite good linearity is required
for the dithering process. The dithering noise properties are also
critical, e.g. if it contains mostly impulse noise instead of white
thermal noise. You may have to move the ADC LSB deeper into the noise
floor, which would reduce the maximum input voltage allowed or require
more bits.

>banks of digitizers, all contained in a small amount of chip real
>estate, and all controlled by a small microprocessor.

The exponent is just the gain in front of the ADC and the mantissa is the real converted data bits. If the exponent bits varies constantly, this just reflects the "AGC" control voltage of the preamplifier. The number of mantissa bits is the critical thing for a radio receiver. The mantissa bits must still be able to represent the broadband noise riding on strong signals. In practical terms, the exponent could only be used to reflect the broadband noise and antenna gain on a particular band and remain constant as long as the receiver is on that band.

Of course, if we could get a true IEEE float data type ADC with 24 significant bits in the mantissa and nearly 1500 dB dynamic range, there would not be much problems in data conversions :-).

While the use of floating point formats greatly simplifies range problems associated with multiplications and divisions, it still does not do any good for additions and subtractions, so you still have to watch for repeated additions of very small values to a large value and possibly regroup the repeated small number additions.

Yes, I found that part very interesting. There are a lot of houses and schools in my area, but there are no specific covenants on erecting structures. I have a cul-de-sac lot and had the necessary room on one side of my house.

So I thought I would check with the city. I was really prepared. My documentation included the designers calculations and California compliance certification. I live in the Phoenix area, but thought that this would be sufficient for approval. California is usually a little tighter on their requirements. Anyway, when I went downtown to the city planners, it turned out that, because the tower and antenna were not for commercial use, and there was no electrical wiring (I use a battery powered electric drill to crank the tower), there were no structural requirements or inspections. So I just followed the manufactures recommendations.

When the tower is cranked down, my antenna nestles itself within a group of trees, and is barely noticeable from the street. Most people that come to my house, don't notice it. This also seems to keep the neighbors happy, and, so far, I haven't had any complaints (knock on wood).

If you go to http://lists.contesting.com/archives/html/Towertalk/ and do a search on "tower base recommendations" you will find some very good discussions on things to consider when erecting a tower.

>part numbers that are of this type? (E.g., from Analog Devices, TI, etc.)

Most of the folks doing FP (for radar work, for instance) use a pair
of converters and successive-approximation logic to do scaling.

I'm also going to point out here that there are two different kinds of
DSP systems being discussed here.

First of all there are audio processors, which take the demodulated audio
from the receiver, digitize it, and process it. This is what the original
poster is talking about, and these gadgets work pretty well to deal with
heterodyne whistles. Some of them also work pretty well on impulse noise,
at least better than the noise limiter on an R-390. There is a wide
variety of them on the market, each of which has an audio-speed D/A and
A/D pair. The dynamic range required really isn't very high since the
AGC of the receiver has done all the hard part for you. 16-bit converters
are cheap and plentiful and more than enough. For the most part, though,
these devices are noise reduction units and can't do much about improving
receiver selectivity or reducing passband group delay.

SECONDLY, and a totally different animal, there are DSP systems that
directly digitize the receiver IF, and do IF filtration and demodulation
in the digital domain. They may _also_ do some audio processing, but
the big deal with these is that they now have very sharp IF filters
without substantial ringing, and they have extremely good demodulation
without a lot of group delay problems in general. These systems require
much wider input dynamic range, which is usually accomplished with
prescaling. These can be found built into the latest generation of
communications receiver, although folks like Watkins-Johnson also make
retrofit units that you could hang off your old Hallicrafters if you
don't mind paying a few hundred times what the radio costs.

2016. Replacement for Motorola FM Dual Conversion IC's

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-04-14 22:09:31 UTC
From: Bernard <bernard.debbasch_removethis_@mail.com>
Message-ID: <vSB7e.6580$lv1.244@fed1read06>
Source record: 19299

I have seen posts on this subject but no definitive answer. Outside limited supply, the MC 3362 and derivatives are gone. If one wanted to start a new design for a dual conversion, narrow band FM VHF receiver (for example a 72 MHz R/C) the options are now limited.

The solutions I have seen mentioned are:

- SA602 + SA615 drawback: 2 IC's instead of one. BTW, are they still mainsteam IC's ?
- Some Japanese IC manufacturers may have some equivalent IC's Drawback: limited documentation and availability

I am forgetting something ?

Note: I don't consider the option of using the limited, often expensive, supply of Motorola / ON IC's to be a good one

2017. Hacking long distance cordless phones to 2m transciever

From: zeb <aurangzebhaque@yahoo.com>
Message-ID: <1113552686.111793.314160@f14g2000cwb.googlegroups.com>
Source record: 19300

Hi,

Has anyone thought about or worked on long distance cordless phones, in converting these to 2m transcievers. Where I live they have these old unsellable Senao sets, readily available. I thought maybe we could use them for 2m.

If someone has info on this his/her help is most appreciated.

I think these are around 200MHz with a power o/p of about 5W or so, from the base unit. I haven't checked more than that, in order for the guy not thinking that he has an interested buyer and thus jacking up the price.

Regards

On April 15-17th, the Shreveport Amateur Radio Association
will run Special Events Station W5E from the Eight Air Force
Museum at Barksdale Air Force Base in Bossier City, Louisiana,
home of the 8th Air Force. The station commemorates the 60th
anniversary of the last combat mission of the 8th Air Force
over Europe. An authentic SCR-287 WWII bomber radio station
and an SCR-274N station will be on the air,
along with other equipment working all bands.
A beautiful QSL will be sent to stations contacted.
More information is available at:

http://www.k5sar.com/HTML/SEW5E.htm

Authentic WWII SCR-287 Station Operation:
While there will be intermittant operation of the
vintage gear throughout Friday and Saturday, on or around
the frequencies below.
The WWII Bomber radio station, SCR-287, running 70 watts of AM,
will operate officially on 3880 KC on Saturday, April 16th from
6 PM until 10 PM Central time, plus or minus 5 KCs for QRM.

There will be a special endorsement to your QSL for working
the vintage station(s). Please note that WWII equipment is
not YeaComWood; some drift and/or chirp may be expected.
We respectfully request the support of the AM community for
our operation of this event. We will also have a complete
and operational SCR-274N station, as well as a display of
the radios used in ferrying operations by the
Women's Army Service Pilots and Women's Army Corps during WWII.

As time and ops permit, we plan to operate the vintage equipment
on other freqs. Look for us around 1845, 3545, 7045, and 7245
(WWII ended in 1945).
Thanks and hope to work you.

Hi,
I built one of these LW/MW/SW/VHF DFMs in the early '80s, and now want to modify the offset settings for use with a different radio. Unfortunately, the circuit & instructions were lost a long tome ago.
Does anyone have a circuit for this unit they could let me have a copy of, or even just details of the diode matrix for setting the offsets?

TIA

TL.

I just noticed in this ad: http://hamstation.com/ybstkftmk5.htm that
Yaesu's FT-1000 finals are MOSETS in push-pull. I don't ever recall
seeing a pair of final tubes in an xcvr or linear in push-pull except
perhaps way back in a very old QST. Can someone explain why push-pull is
used in the Yaesu and why we don't see it in "modern" tube amps?
tnx

Cuz a single 3CX3000A is all you need?

Seriously, tubes are (relatively) high impedance devices and except
for distributed amplifiers, are usually tuned. The high impedance
step down to 50 Ohm requires large transformation ratios that are more
easily implemented with tuned circuits. Push-pull tuned circuits are
a pain in the ass to implement, especially when you want band
switching.

Bipolar and MOSFET amplifiers are by comparison low impedance devices
and are usually untuned. Instead of tuned circuits, broadband
transformers are used for coupling, impedance transformation and in
this case, power combining. The push-pull circuit requires lower peak
supply current and has inherent suppression of even-order harmonics.

With MOSFETS or bipolar transistors, push-pull is easy to get using either push-pull conventional transformers or balanced transmission line transformers. It is easier because of the much lower impedance levels that transistors operate at. The push-pull amplifier has much better reduction of second harmonic output, which makes the low pass filters simpler. Tuned tank circuits are hardly ever used with transistors beyond the QRP level.

==========
Tube amps with 2 output valves can be used in push- pull but then for 1 band
only unless you would switch multiple inductors.
A single valve or multiple valve in parallel can readily output into a
multi-band PI filter arrangement.
In QST -March 1967 , pages 11 - 15 there is an article on a 1kW amplifier
for 50 MHz with 2 pcs 4-125A or 4-250A or 4-400A push pull . This is a
single band amplifier with inductive coupling on in- and output.
Unless you would perform band switching by changing the inductors through
plug-in , switching for various bands would be very complicated.

==========

For example, the internal resistance, Ra, of a triode tube is -

Ra = Mu / Gm

where Mu is the amplification factor and Gm is the mutual conductance.

Typical values for a triode are Mu = 10 and Gm = 5 milliamps per volt
which gives Ra = 2000 ohms.

Corresponding values for a silicon NPN bipolar transistor are Mu =
1000 and Gm = 40 milliamps per volt which gives an internal resistance
of 25,000 ohms.

Typical values for a beam tetrode are Mu = 200 and Gm = 5 mA/volt
which gives Ra = 40,000 ohms.

For a field effect transistor Mu = 1000, Gm = 10 mA/volt and an
internal resistance of 100,000 ohms.

Typically, transistors have higher internal resistances than tubes.
The volts and amps at which they work, the power ratings, are
coincidental and have nothing to do with it except that when comparing
one device with another they should have similar power ratings.

Take a look at their DC characteristic curves. Internal resistance is
the SLOPE of the anode (collector) current versus anode (collector)
volts characteristic for constant grid (gate) volts (or constant base
current).

OK?

And, incidentally, this is the internal resistance which determines whether or not a Conjugate Match exists between the PA device and its load resistance.

Note that it is not under the control of the circuit designer or tuner-upper who is not permtted to change tubes during a tune-up operation in order to obtain a 1-to-1 SWR.

The internal impedance of the device is irrelevant.

My correct previous statement was that transistor power amplifiers operate "at lower impedance levels" because of the lower DC supply voltages and higher DC current, therefore the much lower values of output load and driver impedance levels.

These lower levels make broadband designs easier to accomplish. The fixed-tuned lowpass filters at the output are easier to bandswitch. The old "dip and load" procedures are no longer needed.

Back in the 1950s and 1960s a few vacuum tube PAs were sold that did not use the conventional plate-tuned circuit, but used broadband tranformers. They died an early death, thank heaven.

Push-pull tube amplifiers with link coupled coils etc were very difficult to TVI proof. The pi-network (and pi-ell) with tubes in parallel was a big improvement.

No.

All of this is very interesting, but you are referring to the
devices that are used in the amplifier, while I said, "Bipolar and
MOSFET *amplifiers* are by comparison low impedance.

Well their INPUT IMPEDANCE can be high, but their
OUTPUT IMPEDANCE when used as a power amp is just as
low as bipolar transistors, so the broadband transformers
are just as valid. And as far as their input impedance,
well these are class AB or B power amps, so they take
some driving power. In this case because of the required
driving power, the input impedance isn't very high.

Every now and then a need for a tool not on hand occurs, or
a required part isn't available for a repair. Then the
proverbal light bulb appears over one's head (homage to
Edison no doubt). Today I was running some RG8/U into my
attic crawl space to access a conduit into my shack. I drilled
a hole into the roof overhang and pushed the cable into the
hole. As Murphy would have it, the end of the cable being pushed
into the hole was the end wound onto the core of the spool, so the
cable was very 'springy' resulting in it all bunching up right
at the hole inside the attic. When I climbed into the attic
I couldn't reach the cable, it was sitting in a coiled up bunch
at the wall. No way I was going to be able to crawl the distance
and reach out to grab the cable.

Now for the macgyverism ....
I found a 6 foot piece of left over 1/2 pvc pipe and a 3" U-bolt.
I attached the u bolt to the end of the pipe with electrical tape
and used the new tool to reach and hook the coax.

Ok, I'm sure we've all come up with these macgyverism's from time
to time. Anybody care to share their brainstorms...?

====================================

This little discussion is about the relative internal resistance of tubes and transistors. It has nothing to do with driving resistance which, in the case of tubes and FET transistors, are both very high.

Somebody said the internal resistance of transistors, in general, was much lower than that of tubes. He was incorrect.

Of course, it is possible to find an example of a high power transistor which has a lower internal resistance than a given low power tube.

But, in general, transistors have high internal resistances, greater than tubes.

To base conclusions on the greatly different working voltages and currents of devices is entirely incorrect. But it is easily done and leads to misunderstandings when novices and learners attempt to analyse circuit operation.

It is not incorrect. It is quite correct, and everyone who designs
solid-state linear RF power amplifiers (including me, not a novice) knows
that it is correct. The truth in this matter is perfectly obvious to any
really knowledgeable individual.

I'd have pushed the coax into the 6 foot 1/2" PVC pipe. Then I'd have inserted the PVC into the hole under the eves and into the attic. From the attic I'd have retrieved the end of the 1/2" PVC and slipped it off the coax. Thus, ending up with the coax in my hand and ready to pull and feed into the conduit. Not sure that the hole under the eves would have allowed 1/2" clearance - but might have worked. Just a variation on your theme.

Message-ID: <BKqdnXPgcbEkUf_fRVn-qw@mersinet.co.uk>
Source record: 19327

Hi,

I'm currently having to build some high-voltage capacitors for an auto-ATU that I'm building. The capacitors are made from interleaving brass shim with some kind of dielectric. It was suggested that the dielectric was made from a triple layer of polyethylene sheet (ie freezer bag) stuck together with DC4 grease to exclude any air. However, this seems a messy approach and some engineer friends suggested that instead I use overhead projector transparency. I found that a double layer of this transparency worked to give me reasonable capacitor values with a reasonable number of plates per capacitor.

Now, as the project requires, I fiddled the caps into a binary addition series (1pF, 2pF, 4pF, ... , 1024pF) using a capacitance bridge with a 1kHz oscillator. I was careful to measure the caps in situ so as to take into account any stray capacitance on the circuit board. However, the tuner doesn't appear to be matching as expected (its an L-match). Does anyone have any views on using this dielectric? Is it possible that it has a frequency-dependent dielectric constant so that the cap values as measured at 1kHz are different at HF?

Any comments/help etc gratefully received!

Source record: 19328

When measuring capacitors at HF and UHF you get higher values of capacitance than at audio frequencies. This is due to the inductance and inductive reactance of the connecting leads between the capacitor and the measuring instrument,

Furthermore, the capacitors themselves when connected into a practical circuit, in series with their connecting wires, behave at HF and VHF as if they have larger capacitances than their audio frequency values.

The actual values of capacitors do not change of course.

Large capacitors (1000 pF) are affected much more than small values (10 pF).

The dielectric constants of low-loss plastic insulating materials are constant between AF and VHF. Apparent changes in capacitance are NOT due to changes in the dielectric constant.

On the other hand, what does it matter. When adjusting a tuner one's eyes are focussed on the SWR meter and not on the capacitor values. And the same applies to automatic tuners which don't have eyes.

>Strange. Maybe another resonance mode?

I'd guess the specified frequency is parallel resonance with
the specified load capacitance.

I have some Digi-Key SE3320-ND 60 Khz xctls (C-2 60.000KC-P).

My best try at measuring the series resonant frequency shows
59998 Hz. Perhaps the 60.002 Khz ones are series resonant at
60000 Hz. I don't have any of those to measure.

==========
Have you tried to make capacitors from pieces of double sided fibreglass PCB
material ? Or even better the thin teflon material used for microwave
frequencies (expensive stuff). Because the dielectric material is thicker
,you might need a larger area to arrive at the wanted capacitance.

If you own or can borrow a MFJ 259B analyser ,you can measure the
capacitance at the operating frequency instead of at 1000 Hz.

I would be a little concerned about the loss factor of the transparency
material. The polyethylene originally suggested is an excellent dielectric-
the transparency material may yield reasonable capacitor values, but if the
loss factor is high, wach them smoke.
As suggested, teflon is also excellent.
For the lower values a good qulaity 50 Ohm coax will yield about 29pF/foot.

Message-ID: <4263b3d1$0$11249$636a15ce@news.free.fr>
Source record: 19337

Hi all,

I started a new amplifier project, a 4CX1500B 2m amplifier.
Wanting to make it a bit more state of the art, i want to replace the old meters by Led bars...
The simplest way to do that is to use a LM3914 bar display which can measure voltages with a ground reference.

My design will use a cathode driven, DC grounded screen. So measures must be make "floating" as the ref is the cathode .

How can i achieve this in a simple way ??

How does an ANC-4 work, _as to the phase shift_? Is the one input just split
and one leg run thru a capacitor and resistor to ground, and you select
some linear combination of the two inputs?

That selection then being added to the reference antenna's.

I'm interested in building an 8-input ANC-4, in effect.

The ANC-4 noise canceller works by cancelling the noise before it
affects the receiver AGC circuits. It connects between you antenna and
receiver. A second antenna acts as a noise pickup. The front panel
controls allow adjustment of signal phase and magnitude from the two
antennas to effect noise cancellation. The ANC-4 can also operate as
an active antenna using a noise antenna and noise gain control to
amplify antenna output. And, it can be used as a diversity combiner to
pick up weak signals or null interfering signals. Complete
specifications on the ANC-4 are available from Timewave's web site.

Thanks all, but the links suggested did not have any
schematics, manuals, etc. (www.tenma.com just
redirects to an MCM site with info and price, etc.)

BUT! I called Tenma (actually MCM who sells this
made-in-Taiwan special) and they referred me to
Sypris, who do their warranty maintenance.

There a fine young lady copied the schematic and
emailed it to me. What a surprise, real customer
service, albeit in a round about fashion.

I am ready to jump on that low intensity problem now.

Again, thanks to all and if any one needs this schematic,
just let me know.

Hi Wes,

Thanks for the info. I've looked on the pages you gave me and see that
all measures are made with a ground reference... :(

I will drop a mail to wd7s and ask some suggestions...

Thanks for the answer !

From: Skipp <nospamplease@yahoo.com>
Message-ID: <d40pon$4ij$1@skeeter.ucdavis.edu>
Source record: 19348

You need to have cool air moving across the tube base pins. The
conventional method of under-up cooling supplies the base pins
with safe cooling. If you blow into the anode, what happens to
the air reaching the base pins/contacts? The seal around the
tube base contacts also needs cooling and it should not be already
hot air from passing by the anode.

Smaller tubes are forgiving in cost and operation. Jump to
the 4cx1000/4cx1500 size and you had best not over heat the
tube, both base pins and anode.

cheers,
skipp

www.radiowrench.com/sonic I have a diagram of the Collins 30S-1 available
(as well as many others).

Hi Skipp,

Thanks for the advice.

Yes, in fact must the base be cooled as well !
I don't think the air that will go to the base will be hot, the air will be under pressure in the anode cabinet and the hotest air will be created on the anode cooler and be exhausted almost immediately.

I have seen a description where there are 2 Papst 3472 fans, one blowing and one extracting the air. These fans can produce abt 36 CFM at a very low noise level. Maybe a not too bad idea compared to a squirel radial fan that produces the same volume but at a much higher noise level !!

Any suggestions ??

With traditional FR4/G10 materials you are only going to achieve
Q-factors of the order of 20-30 with a PCB capacitor even on HF, so
don't be upset, if the PCB material generates a lot of smoke :-) even
when exposed with only 100 W of RF power, especially if some high
impedances are involved.

>Or even better the thin teflon material used for microwave
>frequencies (expensive stuff).

Teflon has low losses on HF, tolerates high fields strengths and might
be quite usable material for HV RF capacitors, despite the lower
dielectric constant.

The problem is back pressure on the fan. Most axial fans do not do
well with much back pressure. The flow drops sharply. Squirrel cage
type blowers are usually needed for those type tubes. For a 4cx1000
type tube you need a minimum of a 3 inch wheel on the blower at 3100
rpm and that is with a wide open socket and air path. A smaller blower
would need to be higher speed.

Hi gary,

You're right. But how does a combination of those fans work ?
One "pushing" and one "pulling" ?? The back pressure must certainly be
reduced ?! That's a problem for a hydraulic engineer !! hi hi

Hi Folks,

Anyone out there have the specs on an EEV(English Electric Valve) Variable Vacuum Capacitor
#UC600A-6-70, or failing that, have a cross-reference for it to Jennings, Comet, etc.?? Need to determine the range and voltage.

Thanks,
Butch K4NAU

2071. HF ANTENNA TO SALE - SOMMER XP707

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-04-18 21:13:21 UTC
From: Jos&#65533; Lopes <fartolopes@mail.telepac.pt>
Message-ID: <42642305$0$27122$a729d347@news.telepac.pt>
Source record: 19354

I am interested to sale my hf antenna above mentioned that is in very good conditions.

Reason: need to renew and create a new set up of antennas.

Antenna: Sommer (DJ2UT Beam)
Model: XP 707
Bands: 10, 12, 15, 17, 20, 30 and 40 meters
Balun: The balun furnished with the Sommer antennas is a low-loss air core type using RG142 (BU) Teflon cable. The balun will handle 2.9 kW continuous output at 30 MHz with a loss of only 0.05 dB.
This antenna it still on my tower and working very well.
For price please send one email to:
fartolopes@mail.telepac.pt

The transports costs will be at the resposability of the buyer.
If you are interestes we can sed some actual pictures, and for all the informations concerning gain and front/back, please go to the oficial site:
http://www.sommerantennas.com/beaminfo.html
Best 73, Lopes - CT1CJJ

>
>My best try at measuring the series resonant frequency shows
>59998 Hz. Perhaps the 60.002 Khz ones are series resonant at
>60000 Hz. I don't have any of those to measure.

To help us out, it would be best if you describe your
method of testing the resonance frequencies and the
accuracy of your frequency meter/counter.

A -2 Hz "error" in frequency is about 33 PPM (Parts
Per Million) or 0.0033 %. That seems to be within
manufacturer's stated tolerance.

For what it's worth, the spectral occupancy needed
by the WWVB signal is roughly 5 Hz. That is good
enough to demodulate the AM of WWVB and still
preserve the (relative) sharpness of the digital
amplitude transitions for purposes of obtaining the
correct time of day. Modulation on WWVB is roughly
30% AM at 1 second periodicity.

In my TRF receiver for 60 KHz, the carrier is
extracted by amplifying the filtered signal and
applying it to an over-driven MC1350P which acts
as a limiter. Outside of the (relatively) broad
selectivity of the tuned loop (Q roughly 45) and
an interstage L-C tuned coupling, the final filter
is simply two ECS crystals in series with a small
capacitor to ground at the series connection point.
The capacitor value was arrived at by "cut and
try" substitution, much quicker than trying to
calculate everything after an elaborate crystal

measurement exercise. :-)

The final selectivity is narrow enough to eliminate most of the LF hash around the spectrum, especially the 4th harmonics of the TV set horizontal sweep frequency. That should work equally well on non-limiting demodulation to get the time-of-day data. [without the DSP supplied by the microcontrollers in the radio clocks...we have two commercial units in the house for that]

Measuring the exact crystal resonance frequency is NOT a simple exercise at 60 KHz. I would suggest looking closer at the Digi-Key links for technical data direct from the manufacturer. Those are found on the Digi-Key final part-number page just below the electronic catalog page PDF link. Manufacturer's data yields the parallel capacitance, maximum series resonance crystal equivalent resistance, and either the equivalent series inductance or the equivalent series capacitance. Digi-Key is excellent in their links to manufacturer's data in my estimation.

1/2" pvc is somewhere between 3/4-7/8" in dia, and I only
had a 5/8" drill bit to get into the attic. So pushing the
pvc into the attic wasn't going to work. I had thought of
that though. At one time someone made a thin wall sleeve for
the purpose of lining holes in exterior walls to push coax
through. If you drill through CBS walls and hit a hollow
pocket you will have a problem getting the coax through
if it curls up inside the pocket, hence the sleeve.

The local ham radio outlet didn't have any of the sleeving
though. (Wonder where I saw it...?)

You don't get much pressure relief pulling. Better to push.

Radio Shack sells something of that sort. It comes with a plug at each
end, with an RG-58-sized hole in the plug. The sleeve itself isn't
quite big enough to pass a PL-259, which I found disappointing.

Source record: 19366

Newbie here with a few questions regarding low power FM transmission. Please excuse my possibnle improper use of vernacular. I just purchased a 50mW FM transmitter for playing music in my home. It was built from a kit and sold to a first owner, then sold to me... if that matters.

Since the FCC now uses the guideline of "250mV @ 3 meters" power limitation, one needs to know what their transmission output is. What sort of device would measure this? If I am pushing too much power, can I shorten my antenna (currently 2 lengths of wire coming from the back of the unit), in hopes to lessen the range? The unit is in my basement, which reduces the effective range and possibility of interference with licensed users, but it may still be exceeding the part 15 power output limitations.

Second, if the FCC does "hunt you down" based on complaints, do they issue a warning typically for first time offenders or do they go straight for the $10,000 fine? Or is it purely based on what mood the FCC investigators (or whatever they would be called) are in? I know there are many variables with this, and that they would probably come down harder if you were broadcasting sold advertisements, political propaganda, etc.

Just wondering if I jumped into something to deep.

Thanks

==========

This being a homebrew =home'do' newsgroup ,may I suggest you check the capacitance range with (for example) a MFJ 259B analyser (bought or borrowed). This enables you to check capacitance range at RF frequencies up to 170 MHz.

Max operating voltage can be checked with a 'HiPot' tester which can be homebrewed or perhaps borrowed (local radio club member) If you have other High Voltage components to be tested , it is very much worthwhile to homebrew a Hipot tester.
Have a look at Rich Measures AG6K's website .
I am the happy owner of a Danish made 30kV non-destructive insulation tester ,bought from a surplus store for equiv. $ 30.-
This instrument determines the breakdown voltage (in 3 ranges : 0 - 3 , 30 and 30 kV) of components at a current down to 1 microampere.

2085. Any sources for TDA1572?

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-04-19 17:00:05 UTC
From: Netgeek <no_spam@comcast.net>
Message-ID: <Pb6dna-f1u-NpPjfRVn-hg@comcast.com>
Source record: 19368

Does anyone here know of onesy-twosy sources for the Philips TDA1572T?

The Philips website shows the part is in "full production" status (amazing - part that's not already obsolete 8-)..... however, the only distributor they list (Avnet) shows no inventory. A check of the "usual suspects" (Digikey, et.al.) comes up with nothing and I've had no luck with Google either.

Any suggestions appreciated.
Bill

The FCC is a "Paper Tiger" ever since the gutted the Field Operations
Staff back in the Clinton/Gore Reinvention of Government days. They
don't have enough Field Staff to investigate the Public Safety
Interference complaints let alone any Ham or Consumer complaints.
If you make an absolute fool of yourself, maybe in ten years they might
get around to you, but other than that, it isn't gong to happen.
The FCC has to much Bandwidth to sell, to be worried about any microFM
Transmitters......

I wouldn't go quite that far, there have been some pretty aggressive prosecutions lately. But with a 50 mW transmitter, you would have to be pretty creative at causing trouble to get their notice.

What will get you in trouble is causing interference and then being arrogant about it. So, if you do exceed the field strength rules, there is a remote possibility that some FM station might decide you are interfering with them or competing with them. They might send you a nasty letter. If you stop interfering, it will stop there. If you don't, they *might* shoot of a letter to the FCC and the FCC *might* send you a nastynote. If you write back and agree to stop, and then actually do stop, it will probably end there. However, if you send them back some nasty response, or ignore their letter, then you could be in trouble. Even then there will be proceedings after proceedings before things escalate to the $10K level.

In other words, you not only have to break the rules, but you need to be really stupid about it. It does happen, though. Among amateurs, who tend to know the rules and have the equipment to measure compliance, there are probably one or two prosecutions a month. Those amateur prosecutions usually happen with a lot of help from the ARRL, however. If you interfere with a ham, chances are he will help you figure out how to operate your transmitter without interfering. And if he escalates it to his OO, the local OOC will likely get more technical help to see how you can accomplish your goals in a non-interfering way. If the local section can't resolve it, they will request help from the ARRL headquarters who will also be more interested in solving the problem than prosecuting. All this before Charlie ever learns of the problem.

It really does take an astonishing level of stupidity to get prosecuted, so don't stress over it too much.

However, if you happen to live next door to an FCC listening post or some sensitive government facility, then all bets are off.

I just finished looking at the new ARRL handbook's section on Baluns. I was astonished at how little I understood. The "bazooka" balun described in the book looks like something that does nothing. Anyone know what I don't understand?

Anyway, what's wrong with a simple transformer - primary attached to unbalanced coax line from transmitter, and (grounded) center tapped secondary attached to balanced dipole?

In fact, do I really need a grounded center tap?

There were dual band tank circuits for tube amps that worked on
both 6m and 2m without changing coils. The circuit was made in
both single ended and push pull versions. The push pull circuit
had two separate pick up link coils and basicly was series tuned
on 2 meters and parallel tuned on 6. The 6 meter tank coils were used
as rf chokes on 2 meters. The single ended version used a similar
trick, but was link coupled on 2 meters, and could either be link
coupled or a Pi network on 6 meters.
Source: old ARRL handbooks and VHF manuals from the 50's and 60's.

Sorry for the cross posts. I'm trying to locate someone.

I'm looking for a ham living in Calgary who was going to align my
Heathkit SB-401/SB-303 combo last year (or was it two years ago?). I
lost the email address and phone number --- everything. He mentioned he
could also align my Cardon "Spitfire" as well (if that rings a bell).
I'd like to ship the pair off for alignment now that it's warm weather.

Also, if there is anyone else who can do this, please contact me in case
I can't find the above person.

Thanks very much.

>Are we confusing load impedance with the device equavalent (sic) resistance?

You may be confused, I am not. The OP wanted to know why solid-state amps were push-pull without tuned matching networks while tube amps are usually single-ended and have tuned matching networks. Bill and I offered accurate explanations for this and Reg, as often happens, wanted to inject comments designed to obfuscate the discussion.

Reg also opined, "Somebody said the internal resistance of transistors, in general, was much lower than that of tubes. He was incorrect." I believe that he was trying to put these words in my mouth when of course, I didn't say that, nor did I see anyone else saying that in this thread.

A vacuum tube amplifier operating at Ep = 4 KV, Ip = 500 mA and a 50 Ohm load impedance almost demands a tuned matching network.

An FET amplifier operating at Ed = 50V, Id = 40A is more readily matched using broad-band transformers.

When comparing *one to the other* I contend that the vacuum tube *amplifier* is a relatively high impedance device and the FET *amplifier* is a relatively low impedance device.

As Bill already stated correctly, "The internal impedance of the device is irrelevant."

I can agree with this..... I know of a guy running a transmitter which interfered with an AM station. It wasn't long before the FCC knocked on the "owner's" door and confiscated all his equipment. The stupid bastard didn't learn the first time. He had a repeat performance. The last I heard, he went bye bye. IF they want to find you, they can and will. Make no mistake about it. Cable companies have been shut down due to creating interference to the Aircraft frequencies. Aircraft "is" a "form" of Public Safety. There are other instances. Don't sell yourself short to think they won't come in. You may be "un" pleasantly surprised. I know instances of them busting volunteer agencies for "rules" infractions - things said on the airwaves contrary to the rules. Quite a few "Pirate" radio stations have been shut down recently - as well. So, the FCC "is" out doing what they need to do - even if limited in funds. But - the hefty fines should start building a healthy coffer I would have to think. There have been quite a few very heft fines put out lately and I'm not talking just from the Janet Jackson escapades. I'm talking fines of tens of thousands of dollars for some offenses up to hundreds of thousands for others. Rolling the dice isn't a smart move. The louder the squeak, the more attention it will get. Be a persistent squeak - even if not loud, you'll get attention sooner or later - but it will come.

If you're only wanting to transmit within your house, then you shouldn't need much of an antenna at all. Keep it at the absolute minimum length needed for a clear signal and you should have no trouble. IF it is "still" creating a problem, rather than getting cocky with them, ask for advice, they're likely to lend some advice and see you're trying to comply. Arrogance will draw their attention, like crap draws flies.

(snip)

Perhaps the information on the FCC Website is old, but it currently reads

"Sec. 15.239 Operation in the band 88-108 MHz.

...
(b) The field strength of any emissions within the permitted 200 kHz
band shall not exceed 250 microvolts/meter at 3 meters. The emission
limit in this paragraph is based on measurement instrumentation
employing an average detector. The provisions in Sec. 15.35 for
limiting peak emissions apply."

So, rather than 250 mV/meter you are allowed only 250 uV/meter.

It takes less than 20 nanowatts of power into a practical antenna to get 250
uV/meter at 3 meters. Conversely, your 50 mW into a realizable antenna will
result in a little under 400,000 uV/meter at 3 meters.

Good luck.

John

2105. LCD adapter ?

I think I've found an 6 digit 50 pin LCD that will work electrically with the MM5453N but its a liitle too big physically.
http://www.lumex.com/product.asp?id=1000510

They are $7.26 from Mouser or DigiKey. If the pinout is correct the problem will be the double row spacing. The chip is 40mm between rows of pins while the double row spacing on my Lowe receiver has 33mm and I don't think the LCD pins are long enough to bend and get a fit. The glass is much bigger but I think it would fit. Does anyone know of any adapters, or a way to get this LCD to fit my radio?
tnx

Source record: 19394

Hello all, I am working on a project I had had in mind for some time now, I am looking for input on a certain aspect of it, to be more specific, what would be the best way to collect electricity from 12 dc generator [inductive] at varying voltage, condense it, and release it at a moderated 12vdc at around 300-500 amps? I was thinking maybe a big'ol capacitor and voltage regulator circuit, though I honestly don't know alot about the different types of capacitors and their capabilities. If anyone knows a good way to do this I would appreciate it, or anywhere I could go to find out would be helpful to.

Source record: 19395

How much energy do you wish to store, for how long, and how long do you wish to deliver the 300-500 amp output? It is possible to get high current out of fairly small capacitors, but only for a short time. Batteries generally work better for high energy storage. You might want to search for info on hybrid automobile energy storage systems.

Some simple formulas for (ideal) capacitors:

energy = (voltage^2)*capacitance/2
current = capacitance*dV/dt
where dV/dt is the rate of change of voltage with respect to time

So a 1uF capacitor designed for extremely low inductance and low series resistance, charged to 12V, could perhaps deliver 500 amps, but the dV/dt would be half a volt per nanosecond...at a constant 500 amps, it would be completely discharged in 24 nanoseconds. (The required inductance would be less than half a nanohenry, which may not be practical...) Note that capacitors aren't very good at delivering energy at a constant voltage. "Supercapacitors" (available up to many farads) could be a better option, but may be too pricey for you.

Rechargable batteries are commonly rated for ampere-hours of storage, at a (reasonably) constant voltage, and for maximum charging and discharging currents. A standard 12V automotive battery should be able to deliver a few hundred amps, but maybe not at a full 12V terminal voltage because of internal resistance.

Cheers,
Tom

I think it is revealing that Capacitor Storage is typically rated in
Watt/Seconds and battery Capacity is typically rated in Watt/hours ie a
typical Automotive storage Battery would be rated 100 amps at a 10 hour
discharge rate or about 1.2 Kilowatts hour

A hefty Electronic Photo-flash Unit would be rated at 50~100 Watt-Seconds

If you really believe that the FCC is a "paper tiger," I suggest you keep an eye on this link.

http://www.arrl.org/news/enforcement_logs/

And that's just on the amateur radio side. Granted, they've done a crappy job in that they've been pandering to the nascent BPL industry, but keep in mind that Michael Powell has resigned, and is on his way out. Once he goes, something good may actually happen (for a change).

Keep the peace(es).

I wanted to fish some telephone wire (and later speaker wire for ceiling speakers) over the suspended ceiling in the lower level of my house - about 25 or 30 feet. The clown that built the ceiling wired the supports at every corner so the panels cannot be lifted in order to feed the wire through. I had to cut a couple just to gain access. To feed the wires from one end to the other was easily done using a 30' tape measure. I extended it out to the opposite side of the room above the ceiling panels. It is just stiff enough to hop over obstacles like wires and hangers, ducts, etc.. Once there, lock the tape measure and set it down. Go to the other end and tape the wire to the end tab of the measuring tape. Go back and reel it in - helps if someone else is there to feed the wire. I suppose others have thought of this, but I was patting my ego on the back the rest of the day for doing this.

Ill make it easier next time , in this part of the world certain floor
and wall panels are made crom compressed wood chip , the edges are

grooved and a plastic strip inerted and glued when laying .
The strip is either yellow or red colour delineating hardness and you need one of these strips which can easily be got from building site
I have several which are about 2.5 mm thick by 12 mm wide and 3 metres long the rest is structure dependant.
To get a wall socket fitted you cut a suitable hole in the wall on exterior stuctural walls (but inside in the drywall)walls , insert the strip and push up inside the wall between the frame and bricks , normally with most apllication it will go easily up and when hitting the roof fold over into the roof cavity so when drawing into the roof cavity the wire you attatched is easily pulled into place . On internal walls you drill down with a special drill , I made several from 10 mm steel rod with a suitable fitting welded on to hold a 22 mm spade bit , then drop a weighted string down the hole and measuring with care cut your wallplate hole , easy huh ? . Getting cable inside the roof if its tigth is easiest by taping the cable to a 4 metre 20 mm conduite and poking it across , if poorly accesable lift a couple of roof tiles and off you go , remember to refit correctly .
It can be very hard work and very hot so be sure to drink lots of suitable fluids and I have had to save many from roof cavities after only a few minutesd in our climate . (Ive seen 79 deg C on a hot day in a roof)

"Paper" tiger = "paper" bites. They can be painful. A big bite via paper -
called a citation. That "tiger" could take a big ole bite out the paper - in
your wallet.

As the man said, they may have dropped the ball on the BPL, but they've been
sticking it to quite a few - with fines. I sure wouldn't be so quick to sell
them as being dead when it comes to enforcement.

Doesn't take many "monitoring" sites, when the fingers are pointed towards a culprit, then they can move in for the kill - collecting evidence. If they get enough bitching of a problem, they'll come knocking. It doesn't take a rocket scientist to pinpoint a signal. Many Hams and/or 2 way radio shops have the proper equipment to do the job. I've tracked a few signals down in my time thus far and also filled out papers to the FCC for stations "accused" of interference by a neighbor.
And, there are often "weekly" lists of "Radio Stations" busted for violations. They can't be sitting on their ass and doing this stuff! As I said, don't count them as down and out.

Source record: 19257

More than a year ago I downloaded a copy of the circuit diagram
from the Timewave website. My interpretation of the diagram is
that the noise antenna goes to Q1 that has a transformer-coupled
output whose phase, relative to the input, can be shifted by varying
R6. From there the phase-shifted 'noise' is applied to Q2 and a
portion of the output, determined by R12, passes to Q3, probably
a buffer stage. In T4 the phase-shifted 'noise' is combined with the
main antenna signal to give the desired output. I hope this explanation
is generally correct and is of some use.

>>> I'm interested in building an 8-input ANC-4, in effect.<<<

This may or may not be of interest but here it is anyway. Doug Demaw did construction articles in the May 96 and July 97(improved version) issues of CQ for a "QRN Squelcher". He did a similar article in Monitoring Times but omitted the TR switch He compares this unit as an equal to the ANC4.
I ordered the circuit boards for the project from Far circuits (www.farcuits.net) but haven't started the project yet, saving it until I finish some other already started projects. RM~

PS, Far has the boards listed in the Audio section of their online catalog and they will supply a copy of the CQ article for an extra $1.50.

2126. Help Identifying RF Power Transistors ?

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-04-22 10:41:39 UTC
From: skavanagh73@yahoo.ca
Message-ID: <347cf68.0504220241.7e423657@posting.google.com>
Source record: 19259

I have a surplus board containing a number of RF power transistors.
The board is marked "65W PA" and appears to be for VHF or UHF FM
(bases are grounded). It appears to be of North American manufacture.
I removed the input transistor years ago. There are 4 stages left.
All use flange mount transistors with round ceramic cases (two devices
in push-pull in the output stage). The first (remaining) stage uses a
device in a .380" diameter 4-lead case. The rest are all 0.500"
diameter 6-lead cases. Each transistor has four lines of marking on
the case, which read as follows:

Stage 1: 947 7249-2 7901 C
Stage 2: C 185 281-1 912
Stage 3(driver): 947 7282-2 7200-9 C
Stage 4(output): C 185 283-2 008

Can anyone suggest part numbers for these transistors ?

Keystone 1220 is 0.125" diameter and 0.5" long overall, but only 0.379"
from collar to tip. Keystone 1210 is .566" from collar to tip.

1230 and 1231 are similar for 0.156" diameter.

Tim.

National Semiconductor has a high voltage application note in the PDF which describes the product.

Or you could use an opto-isolator (an analog version like the HCNR200) to read the voltage across a shunt. You will need a drive transistor because the usual opamp suspects won't be able to provide enough current for a LED bargraph.

I have a new rf deck with LPF,BPF and PA for a M700 HF transceiver. I think it is rated at 150-200 watts. It is mounted on the black finned heat sink and has all cables and connectors to plug into a low level rf source. I had planned on using it with a SDR1000 transceiver but have since changed plans. $75 plus UPS.

Leon,

Looks like you're doing some interesting things with these DSPics. I'm curious to know if you've had a chance to use some of the Microchip tools (e.g. their digital filter package) and what your impressions are.

OTOH, if you're using something else - what can you recommend?

Regards,

Bill

It works the same way as the one on the Hallicrafters (or was it Hammerlund)
receiver back in the 1940/50's. Odd that the rice boxes don't come with one
already built-in---they are not complicated circuits.

Vic Misek has a couple of circuits in his Beverage Antenna Handbook. He
uses them to null steer parallel wires or two-wire Beverage antennas

Haven't tried it yet, I just used some dsPIC code written by someone else
for the bigger 'F6014 on the dsPICDEM 1.1 development board. I'll be
creating my own filter coefficients and will try the Microchip software.
I've used Scilab in the past for FIR filter design, and a few other
programs.

One problem with the 'F4013 is that any software using the codec interface
works OK under the ICD 2 in-circuit debugger, but not when actually
programmed into the chip. I'm waiting for a response from Microchip about
it.

Why not just download some DSP software, hook an audio out to the line in of
your computer sound card and try some processing for yourself?

Regards,
John

Source record: 19273

Hi John,

Thanks for the answer and suggestion.

I have the LM3914 datasheet and since my first post, i've had a serious brainstroming about the way to do that.

The best solution is to use a HALL current detector, then the rest of the measure can be completely isolated. ALLEGRO makes very nice small things but only for higher current. The smallest is for +/- 5A with 133mV/A sensitivity.

Otherwise i could use an OP amp followed by an optocoupler HCNR200 or IL300 with a feedback. Linearity is then almost perfect But i still have to supply the OP amp on the "hot side". The display part would be completely isolated.

Last guess is to use as you suggest an opto coupler via a shunt on the hot side. Nothing to supply and everything is isolated. Best is a FET opto coupler like the H11F1

The problem is to know if i will be able to measure low currents. The screen has max a few ten of mA. At what current will the opto coupler start to light and what the transfer is?

Did anyone play with this ?

Patrick.

I have a nice collection of panel meters 16 total for sale.
I will only sell as one lot as i do not wish to make a bunch of trips to the PO. I hope you can understand. All measurements are of the FACE not the Hole cutout.
I will list L/R as pic shows. 1)AC AMPERES 0-15 Simpson 3"x3" 2) AC VOLTS 0-500 Simpson 3 1/4"x3 1/4" 3) AC MILLIAMPERES 0-10 3 1/4"X3 1/4" Simpson 4)KILOVOLTS DC 0-5 Weston 3"x3" 5) AMPERES DC 0-50 Simpson 3"x3" 6)AMPERES DC 0-30 Westinghouse 3"x3" 7)VOLTS DC Weston 0-200 3 1/2" 8)AC VOLTS 0-50 Triplet 3 1/2" 9) DC VOLTS -10-+10 0 CENTER 2"X 3/4" 10)DC AMPERES 0-5 Shurite 2 5/8"x2 5/8" 11) AC VOLTS 0-300 Shurite 2 5/8"x2 5/8" 12)DC VOLTS 3 SCALES 0-1000 0-400 0-200 Westinghouse 4"x4" 13)DC MILLIAMPERES 0-500 Hickok 3 1/2" 14)DC MILLIAMPERES 0-200 Triplet 3 1/2" 15) DC VOLTS 0-300 Weston 2 5/8" 16) AC HOURS IN USE 240 AC Engler 2 3/4" All meters do work and in nice shape. Some of these are hard to come by, I would like 125.00 shipped for all OBO. Can do PayPal.

Pa> Did anyone play with this ?

Patrick, optocouplers are as sensitive as the light from the internal
LED. I'd roughly estimate the lowest end LED current at about 0.1mA...
but would have to count on at least 1mA to be sure it was lit.

I'm looking at a spec sheet just now and that is roughly ballpark,
since the graphs start at 0.1mA. The one I'm looking at starts the LED
current vs collector current at 0.3mA vs 0.1mA. That is about 3 times
less than I expected. Keep in mind a minimum 3 volt LED voltage drop.
The isolation voltage is pretty good at from about 1500 to 3500 volts.

BTW I really like your brainstorm idea of using a Hall Effect device
but I don't know what the typical sensitivity of these can be.

I think the sure way is to have a floating source of voltage to power
the sending circuit, either a little battery or an ac transformer with

rectifier supply.

A*s*i*m*o*v

... I think my learning curve is a circle!

FS: Ryan Communications 30 meter CW-QRP transmitter. Milliwatts to five watts with 9 volts to 14 volts. Comes with an extra final & a crystal for 10.106 MHz, the 30m QRP stand-by frequency. FULLY assembled and two different size crystal sockets are on the tx board. I use my three other Ryan transmitters with my Sony 7600 receiver and it makes for a great little portable ham station. ONLY $29.95 w/ crystal, instructions and extra final amp transistor!!! (Plus $5.95 First Class USPS mail & insurance.) wa8mea@hotmail.com.

If you have not already bought the accessory- skip it. By far the worst implementation of a dip meter I have ever seen. At the other end of the scale is the Measurments Model 59, commonly available on EBay.
With it, you can dip the center of a 36" rod- and see a HUGE dip even while inches away. The MFJ can't find it if it's on top of it- and most others aren't much better.

> manufacturer's stated tolerance.

I see what you're asking.

The Digi-Key pages says 100 ppm (+/- 6 Hz @ 60 Khz). The Epson
web page says they are photolithography-finished and at least
one Epson data sheet says the standard frequency tolerance is
20 ppm. Possibly they have no problem hitting 20 ppm and the
actual tolerance is much better than that (but not over
temperature).

20 ppm is still 1.2 Hz wide and the resonance probably is
sharper than that (Q > 50K?).

This measuring project started when I tried to use the Epson
crystal data to calculate what the series resonant frequency
would be of the 60 Khz parallel specified crystals. After
much mucking around with various numbers I decided to measure
it.

And you're right, I've been ignoring calibration. Here's how
I'm measuring the resonance:

I have a homebrew LC VCO running at 6 Mhz. It's full frequency
range is about 5.99180 to 6.0053 Mhz. This is divided by 100
(two 74LS90's) and then low pass filtered resulting in a sine
wave around 60 Khz.

The signal level is attenuated via 10k/1k resistors and then fed
through the crystal with a 10k load on the other side. There's
some additional loading from the x100 gain amplifier and then
into a scope.

The circuit around the xctl looks like:
.1 10k
from-e-follower-lowpass--||----/\/\/\/\/----+---| xctl |----+---> to
x100 amp
< >
> <
< 1k < 10k
> >
< <
gnd gnd

I can see a noise widened trace on the scope plus some
switching spikes/artifacts. As I tune the VCO, the noise
trace is flat except at one specific frequency, which is
about 1 Hz at most wide where the noise band becomes a sine
wave.

I'm measuring the frequency of the 6 Mhz VCO with a
Ramsey C-125 frequency counter. It's a standard ICM7216D
counter with a cheap 10 Mhz crystal as the time base. It's
uncalibrated (other than the factory, not sure of the date,
possibly in the 70s?).

Ok, how to calibrate the frequency counter?

And how stable is the frequency counter?

I'm living in a cloud of RF noise, plus computers. In addition
the frequency counter is a real RF noise generator too
(multiplexed LEDs in addition to the counting circuitry).

By moving the counter and short wave radio to a different room
I managed to hear the 2nd harmonic of a 5 Mhz crystal oscillator
on 10 Mhz with WWV. It sounded like the beat frequency was lower
in frequency than the 100 Hz WWV modulation pulses. So an upper
bound of +/- 100 Hz at 10 Mhz would put the upper bound on the
frequency counter of 10 ppm.

I'm not really happy with this calibration, I'll have to see what
I can do to improve it.

I have been toying with pen and paper...
It looks like like the grid circuit to the 6CW4 could have an isolation capacitor inserted to remove and DC bias from the gate of the replacement fet. And, the plate of the 6CW4 circuit could have the B+ side of the rf xfrmr moved to a low volage supply (perhaps rectify and filter a 12v AC heater supply to supply the new voltage.)
And, a proper bias supply constructed to supply a necessary bias to the gate...
And, ideas?

I've seen works on "transistorizing" tube radios, but the
characteristics of tubes and transistors are sufficiently different that
in general you have to approach this on a case by case basis. So while
I don't think you have any hope of making a plug-in compatible 6CW4
replacement, I _do_ think that you could often use most of a circuit
designed for a 6CW4 with some other device.

Having said all that, I would probably either buy another 6CW4, or
design & build a new circuit inspired by the old.

Yes, that is exactly what is occuring here, a "new" circuit is being designed... and, a turns ratio change may have to be contemplated in the drain circuit (existing rf transformer)--not the gate circuit, that existing circuit, decoupled through an isolating cap should be just fine (the fet is a high input impedance device)--this is the front end of a receiver, the actual signal levels here are low...

But, I am interested, what roadblocks do you see to "I don't think you have any hope of making a plug-in compatible 6CW4 replacement..." ?????

Warmest regards,
John

Even though a FET and a tube bear superficial resemblances, the FET is a
much lower impedance device, with different restrictions on allowable
gate (grid) voltage, drain (plate) voltage, source (cathode) currents,
etc. The interelectrode capacitances are, in general, markedly
different and the whole FET circuit operates at a markedly different
impedance level than the tube circuit does. If that weren't enough the
mechanisms by which the tube gain drops off as frequency increases is
different than those for the FET, and the general circuit behavior of
the two changes differently as a function of frequency.

Yes, and most of that would be taken care of just by choosing an "rf fet" as compared to an "audio fet."
At least in the circuit I am looking at, the 6cw4 is operating at in input impedance of ~500K-1 meg--the fet circuit will of course, expect 1 meg--no sweat for a even a cheap rf fet...
As mentioned, the blocking cap removes all question of danger of HV bias (I will supply the bias--most likely though a resistor bias arangement (perhaps clamping it with a diode if there is any danger of damage), and the power supply mentioned removes all danger of high B+ voltage...
This 6cw4 is the preamp in a frontend, signal levels are very low, there is a buffer stage following, with an amp behind that... certainly a signal level compatible with a small signal fet...
The 6cw4 is a "hybrid" device... I am looking for a datasheet on it now, I think replacement will go quickly and be simple, probably not even requiring revamping of the rf xfrmr on the drain (will revamp if noticible degrade in preformance....)

I was just hoping someone had walked this path before and could speed my way and hold my hand....

At this point, I am simply wondering, "Why hasn't someone done this before!"

Is there a big call for these devices? Perhaps I can build them and market them on Ebay... <grin>

Warmest regards,
John

Hi John,
Guess I'm just a boatanchor fan and would leave the circuits alone-
especially if there is no improvement in functionality.

well, that is fine, however if you don't have a 6cw4 this fix would be a God send...

I don't know of anyone making them anymore, like the gold, the timber, the water, and like oil, an end will come...

But these rigs can still live on...

I can't provide any references, but converters and preamps were some
of the first things that were transistorized. They were simple with
a single stage or at most a few, so once FETs came along they were
put to use. ON one level it was likely just to try it, but of
course the lower noise figure probably was a lure.

Given that that there might have only been one tube in the thing,
probably many were treated just as a foundation without much concern
for a direct plug in. I can picture an article in "73" from 1967
where someone talked about putting an FET in a nuvistor preamp, and
it wasn't much more than shorting out the cathode resistor (or something
like that) and a returning. The basic scheme would be the same
whether it was a triode or an FET, so it certainly is a relatively
easy thing. The same article had the author putting FETs into
other things, like a Command set transmitter, or rather the VFO
section, and that too was pretty simple.

Decades ago, I got ahold of some Collins PTOs that covered the
broadcast band, and I didn't have to do much to put an FET in
them beyond soldering in the FET and running the thing off a
12V or so supply.

It tended to get more complicated with multiple stage units, or
perhaps just that it ceased to be easy to put it back together
if it didn't work right. There'd be articles about conversions
that sometimes were about replacing function, some about modifying
the circuitry so the FET or whatever would fit in, and of course
the simplest (for the equipment, but not so much for the replacement),
a universal plug in.

well, it works, there was a 1k resistor bypassed by a .01 cap on the cathode
of the 6cw4, I just hooked the source of the fet to it, adding a 500 ohm
resistor to the drain which passes though the primary of a rf xfmr feeding
the next stage, it is fed with ~16V B+. Works great, since the 6cw4 was bad
there is no way to compare how this affected preformance, but receive seems
hot... noise level good...
Even if a dozen 6cw4's dropped from the sky, I'd just look at 'em....

Michael:

As usual, I am behind the times--would have been a great article to write up
back in 1967, huh? <grin>

Thanks for the encouragement.
The fet I used only has house numbers but it came from the parts box where I
keep hf rf parts--obiviously a N channel fet--it works great....

Source record: 19296

It should be remembered that FETs are a voltage controlled
current device. A tube is a voltage controlled voltage device.
A bipolar transistor is a current controlled current device.

A FET is therefore somewhere in between a tube and a transistor.
I did have some luck with a FRG7000. the IF (which does all
the work in a radio) was connected in the old triode configuration.
Signal to the 1Meg gate and the drain working into a parallel
IF can. I had a good look and the designers had used regular
transistor IF cans but ignored the tapping on the output side.

By cutting the tracks and making little jumpers i was able to
boost the rx signal by using the tap on the coil to the drain. I had to
put caps in to connect to the next stage - the IF cans were now working
as voltage transformers and improvement in reception was dramatic.
What was a 'deaf' reciever was now pretty useful.

Anyone wanting to use FETs for tube replacements should remember
they aren't voltage amplifiers - only current amplifiers.

Hope i have made myself clear? :-)

A tube is also a voltage controlled current device because of its transconductance (gm) as well as a voltage controlled voltage device because if its amplification factor (mu).

A FET can be thought of in the same way if the gate is not forward biased. MOSFETs are even more closely related. The difference involves the way that the device is used. In some transistor circuits the "topologies" are amost identical to tube circuits.

FETs almost always operate at lower B+ voltage than tubes, so drain voltage max-to-min swings are smaller and drain current max-to-min swings are greater, which suggests lower values of drain load resistance.

Fifty years ago I designed pulse amplifiers at work (GE)for nuclear event detectors using the 6CW4.

At one time special low plate-voltage (12.6V) tubes were made for car radios in order to eliminate the high voltage power supply that used either vibrators or the 0Z4 tube.

Yes, quite, and ohms law makes it plain that current through a resistance
causes a voltage drop across it...
And, logically following, a voltage placed across a resistance causes a
current to flow through the resistance--
hey, this is excellent idea for a voltage-to-current/current-to-voltage
conversion device--ya suppose someone else has thought of that??? <grin>

And I seem to recall there was even a Nuvistor or two that was designed
for low voltage operation. I can picture an RCA "Ham Tips" that had a
mobile converter using them.

Michael VE2BVW

2167. Shielded inductors -- why do they work so well?

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-04-26 15:24:15 UTC
From: Joel Kolstad <JKolstad71HatesSpam@yahoo.com>
Message-ID: <116sn92hsqv3b45@corp.supernews.com>
Source record: 19201

I've noticed that the various tunable inductors (and transformers) in a metal can are much better shielded than I might have initially guessed, based upon the premise that most all of the flux from the coil in concentrated inside the coil which is 'visible' through the hole in the can (so that the thing can be tuned!). In thinking about this, I've pretty much convinced myself that the shielding works as well as it does because electrically it still "looks" pretty much contiguous at the frequencies you're typically operating the coil at (e.g., tens of MHz for a 1/4" hole), in a similar manner to how perforated enclosures make an effective shield so long as the holes are small enough (...and how you can even calculate the attenuation based on "waveguide below cutoff" formulas).

Is that correct?

If so, it seems that if you tune the slug so far "out" that it protrudes from the top of the can, you're probably starting to seriously degrade the shielding... right?

Thanks,
---Joel Kolstad

2168. Re: Replace 6CW4?

From: John Smith <assemblywizard@gmail.com>
Message-ID: <a3tbe.120$oz4.4782175@news.sisna.com>
Source record: 19200

In the circuit I revamped--a varying current through the primary of the rf xfrmr causes a varying current through the secondary of the rf xfrmr--at the same time--the current is made to vary because of the voltage placed across the primary and the voltage caused in the secondary by the current which has been induced there... these actions being caused by the amplification of the fet...

While one could look at it--that this is current amplification which is occurring--the current holds a direct correlation to the varying voltages occurring... and I didn't count the turns on the xfrmr!

My final analysis, "Hey, IT WORKS!!!" <tongue-in-cheek-grin>

Warmest regards,
John

>
Think current in a shorted turn.

In order for magnetic field to protrude through a hole, current is
circulated around the hole, like a shorted turn around a transformer.
If the L/R time constant of the turn is much longer than the the
period of the cycle, the magnetic field caused by the shorted turn is
almost exactly equal and opposite of the magnetic field trying to get
through the hole, and the two fields almost perfectly cancel. If the
slug protrudes through the hole, though there is a slight increase in
the external field, it makes more current circulate around the hole,
and reduces the inductance of the coil a lot more since this more
effectively couples this shorted turn to the rest of the coil.

Zero-beat to WWV is hard to do better than 50Hz by ear. Mechanical aids will get you a little better but then at the few Hz level you hit variations in carrier due to ionospheric variation.

For a few hundred $, HP Z3801A's are available on the surplus market. They're a 10MHz OCXO locked to GPS. Short term Allan variation is 10^-12 or better over 1-100 seconds. Many lab counters and a lot of ham radio frequency counters will happily accept the 10MHz reference that the Z3801A makes.

Other telecom-related GPS-locked OCXO's/rubidium oscillators are available on the surplus market too, some make telco-related reference frequencies like 1.544MHz or 19.6608MHz which can be used to calibrate on.

Tim.

Or go to Ameco on Ebay- where you can buy a CN- converter for $10 and p/u three at a shot. Some years back I laid aside a pile of 6CW4 and 6DS4's + sockets awaiting a nice homebrew project.

Along the same lines the John P. took, think of a coil inside a shield which has no holes. It is current that the coil induces into the shield which results in a field which cancels the coil's field external to the shield. Now, where does the current flow in the shield? Is there any significant current flowing in a little disk of the shield which is on-axis with the coil? I'd say no, most of the current is around the shield just outside the coil. So if you remove a little disk which has "no" current in it, have you disturbed the magnetic fields? And if you haven't disturbed the fields, have you reduced the shielding effectiveness?

Cheers,
Tom

Mu> From: Murray <me@erewhon.com.au>
Mu> Xref: aeinews rec.radio.amateur.homebrew:9477

Mu> It should be remembered that FETs are a voltage controlled
Mu> current device. A tube is a voltage controlled voltage device.
Mu> A bipolar transistor is a current controlled current device.

Mu> A FET is therefore somewhere in between a tube and a transistor.

If we look at the characteristic I/V plate curves for a pentode it is
easy to see a similarity with the collector saturation plots of a
transistor. The FET in my opinion is different from the pentode
analogy but it is a little more like the triode.

The combination of bipolar transistor and FET is called a BiFET and
this is perhaps most like a pentode than anything. There is also power
HEXFETs which are something amazing with extremely low ON resistances
in the milli-ohm range. These might be more like a triode on steroids.
These come in pretty high voltage versions which seem to me more
suitable to replace a 6CW4 with some bias voltage adjusting of course.

Thanks for the responses, Tom and John -- it makes more sense now.

I do wonder how much of the shield could be removed before the shielding effectiveness would drop significantly? I believe that some transformers are shielded just by having a large metal band that covers perhaps 2/3 of the transformer's area, right? ...and presumably they're still quite efficient.

In a solenoidal, helically wound coil, most of the magnetic flux is aligned with the center of the coil and flows along the axis of the coil. Relatively little flux is outside the coil because of cancellation effects. For a single turn, current in different parts of that turn tend to partially cancel flux in regions that are outside that turn.

To see this, draw a circle of wire and show a current at one point flowing in one direction (out of the page). At the corresponding point diametrically opposite, that same current flows in the opposite direction (into the page). Inside the turn the two magnetic fluxes that encircle the wire add in-phase, but outside the turn these same fluxes cancel in opposite phase. This effect is more pronounced in a coil of small diameter.

Coils of that kind are pretty well self-shielding for regions beyond the *side* of the coil.

But if a copper disc is placed near the *end* of the coil a large circulating current is induced around the edge of the disk and a flux is created that opposes the flux inside the coil (Lenz's law) and a significant reduction of the inductance of the coil can occur. This effect has been used to "tune" coils.

The completely enclosed metal shield helps to create a closed path for leakage current that makes the shield much more effective.

The shield around the coil can also reduce capacitive coupling to adjacent circuitry. This is often important.

I have some teflon insulated, silver plated stranded 22AWG wire for
sale. It is in 10 fifty foot rolls (500feet total)
At least five different colors. No choices of colors. The wire is rated
200~C and 600V.
Great for audio, solid state or tube applications, boat anchor repair or
new construction. Price $14 per 500' assortment.

Shipping $4 for lower 48 states
Shipping to Canada $11 for Global priority mail.

Would like to sell some before going to Dayton to free up some dough for
more radio stuff :)

The flux at the center of the coil is highly concentrated. This flux then leaves one end of the coil and returns to the other end via an external path, just as it is supposed to do, but at a much smaller value of flux *density* in the external path. This external flux can induce "eddy" currents in a shield that can decrease coil inductance and Q, usually only a small amount if the shield is not too "close".

This is in addition to the things mentioned before.

Have you compared the capacitances of the 6CW4 and Hexfet? Note also that the FET capacitance is highly nonlinear, varying greatly with reverse junction voltage.

==========
The above sparks-off my following question:

If an antenna matching unit (some prefer calling it a tuner) has air
/ceramic/polystyrene wound inductors ,to which extent will a metal cabinet
affect the Q of the said inductors ?
I have read somewhere that to maintain the best possible Q , the distance
between the inductor(s) and other metal parts should be not less than the
diameter of the inductor. Does this make sense ?

TIA for any response

I prefer the term "tuner" because the unit very seldom actually "matches" impedances. Instead, it "transforms" the impedance at the sending end of the transmission line, coax or whatever, to the 50 ohms resistance that the transmitter is usually (these days) designed for. The term "tuner" is common usage and it's OK.

The coil in a CLC tee-type tuner can have a Q as high as 400, and stray coupling to the metal cabinet or ground plane can easily cut the Q in half. What effect that has depends on the load impedance of the antenna feedpoint. If the load is highly reactive (high X, low R) the coil can get quite hot.

I believe it is important that the open ends of the coil should be at least one coil diameter away from any metal surface. The sides of the coil are less critical, but the mechanical design should do a pretty reasonable job of reducing that stray coupling to a low value also.

Stray capacitance from coil to ground or elsewhere can be a problem sometimes.

I have been thinking about my previous inputs to this thread, and I am not entirely satisfied with them. I will try to improve them sometime today.

Check out the latest Atlanticon proceedings, or the upcoming issue of the
Homebrewer for a circuit to allow you to see zero beat to within a fraction
of a Hz.

Hi Bill,

In practical tuner applications the unused part of the coil is usually
shorted. The reasoning is that it prevents the generation of high RF
voltages. Shorting part of the coil should ruin the Q quite a bit.
Any comment on this practice?

Thanks, Peter

You certainly have your mind strolling down paths I have wandered...
Yes, it does seems so--is that found to be true when carried into actual construction practices--well, yes and no, but not to any extent which poses a "real" problem...

Or, simply put, I no longer lose sleep over the fact my L-Tuner shorts turns when tuning the coil...

Regards,
John

Source record: 19223

Some years ago I found that leaving the unused turns open-circuit caused very serious interactions with the remaining part of the coil at certain frequencies, and actually made the tuner untunable at those frequencies. I was sure that the open turns and the capacitances involved with those turns was resonating, causing "suckouts". If the unused turns were shorted, the spurious resonances in the coil disappeared, a well as I could determine.

Assume the shorting bar is perfect (lossless). Then:

The equivalent circuit just for the coil alone is the used part with its resistance, magnetically coupled to the shorted part with its resistance. The coupling from the shorted part to the used part adds an inductive reactance plus some resistance in series with the used part. The shorted turns have nearly the same ratio of inductive reactance per inch of coil length to resistance per inch of coil length as the rest of the coil, so the Q should not be degraded by this coupling. In other words the net loss is the same as that of the entire coil operating alone. The perfect short does not add power loss into the coil.

Assume the shorting bar is not perfect (not lossless). Then:

Some additional power loss is added to the shorting bar and the Q should decrease.

New Program "TWINTUNE.exe"

Using a tuning capacitor across one end of a balanced-twin line with a
short circuit at the other, the combination of line and capacitor
behaves as a high-Q parallel-tuned circuit.

Applications include push-pull VHF power amplifiers and power
oscillators.

The program also assists with design of ordinary HF balanced-twin
open-wire transmission lines. Zo and attenuation is computed.

Download program TWINTUNE from website below in a few seconds and run
immediately.

Try Vectron International (formerly Croven). They will make crystals to
order, but it will cost you. I do not know anything about the name
change, but Croven crystals were, and probably still are, the best that
money could buy.

I think your problem is your bias circuits.
I suppose you are trying to measure S-parameters at a fairly high frequency.
Your inductors are way too big. Such large inductors will have resonances
at very low
frequencies. If you can, do away with inductors in your bias networks all
toghether and use high value
resistors. At the minimum, use much smaller inductances that have resonant
frequencies several times the
frequencies of interest. What you really want is resonances at frequencies
larger than the ft of the transistor.

reguards,
Cliff

A followup to my previous input:

I connected an old roller coil with short circuited turns to my ancient
Boonton 260A Q meter.

Over most of the inductor range at 10 MHz the Q remained "fairly" constant.
At the low values of inductance the Q (about 250) dropped about 15%. I
suspect changes in shape factor of the unshorted turns are involved. The
winding pitch of the coil is greatly reduced at low L values to try to
maintain shape factor and improve Q. At low L values, inreasing the
frequency to 15 MHz helped to restore most of the Q.

The detailed analysis of all that is going on in the roller coil is a
time-consuming chore that I don't want to get into. I believe my previous
explanation is OK under ideal textbook conditions (Kraus "Electromagnetics"
4th edition page 235, Eq 2) but of course that is just an approximation to
the actual coil, as could be expected.

On to other things.

International Crystal, of course.

Beware, however. These people are perfectionists and simply specifying 268.435 MHz isn't enough. The oscillation frequency depends on a number of factors, and they will expect you to know all about the circuit you are going to use the rock in.

Sounds like a mighty high frequency rock, though. If such a thing can be made, don't expect it to be cheap.

-I have ordered crystals from www.eska.dk on several occasions. The highest frequency one they've cut for me was approx. 150MHz (LO in an AIS receiver w/10M7 IF).

Worked a charm and didn't cost too much, either. Think I paid approx. EUR15 a piece at 10pcs and two week delivery.

Thank you all for advice.
Yes i know that just frequency is not enough for ordering a crystal.
The only problem is that in general the minimum lot is 10 pieces!
The need is for a DDS with AD9951. At that freq the microcode to drive the DDS will be very simple: i'll have just to enter the freq and shift a register 4 time.
No multiply or division that usually are slow algoritm. And resolution will be 1Hz.
Thank again.

I have an Icom 251A 2M all mode rig. I did a mod today to cut back the power to about 100 mW when I have a transverter connected to it. When keying up in SSB mode with no audio applied, I get approximately 10 mW of carrier. I want to null this out to an absolute minimum. I see IC4 on the main board is the balanced modulator. My guess is R270 on the main board. Can anyone with a service manual confirm this? Thanks!

The "plate" (well drain) curves of a jfet have nearly the same
slope as a pentode tube. So replacing a 6cw4 with a jet would be
like sticking in a 6ak5 (or similar) tube. The big difference
between a fet and a pentode is that you can change the slope of
the curve somewhat by varying the screen grid voltage, you
can't do that with the fet (the screen voltage is built in and
fixed).

Reminds me of early regenerative receivers built with fets.
It was quickly discovered that varying the drain supply voltage
to control feedback didn't work very well (it won't work with
a pentode either!). So most fet regen sets used a throttle cap
to control feedback. You would be better off putting a pot

in the source circuit to raise it above ground, thereby increasing
the gate bias. This would move your operating point down to
a lower curve, reducing gain. But I digress....

My point is that fet's are more like pentodes than triodes, keep
that in mind when you make a circuit change from tubes.

| The "plate" (well drain) curves of a jfet have nearly the same
| slope as a pentode tube. So replacing a 6cw4 with a jet would be
| like sticking in a 6ak5 (or similar) tube. The big difference
| between a fet and a pentode is that you can change the slope of
| the curve somewhat by varying the screen grid voltage, you
| can't do that with the fet (the screen voltage is built in and
| fixed).
|
| Reminds me of early regenerative receivers built with fets.
| It was quickly discovered that varying the drain supply voltage
| to control feedback didn't work very well (it won't work with
| a pentode either!). So most fet regen sets used a throttle cap
| to control feedback. You would be better off putting a pot
| in the source circuit to raise it above ground, thereby increasing
| the gate bias. This would move your operating point down to
| a lower curve, reducing gain. But I digress....
|
| My point is that fet's are more like pentodes than triodes, keep
| that in mind when you make a circuit change from tubes.

2211. dsPIC audio processor

I've posted some pics on alt.binaries.pictures.radio
This may be a one of a kind individual homebrew effort for 10 thru 75
meters, eight band ssb receiver with about 30 tubes and mechanical filters.
If anyone knows anything about it, I'd sure like to know. There are some
disconnected wires and a some tubes missing. The guy I bought it from
thought someone in Alaska made it. I had to buy the ssb 6146 Tx to get it
and will post pics of it.
tnx

2216. StereoZoom microscope repair

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-05-02 19:15:51 UTC
From: Chuck Olson <chuckolson01@REMOVETHIScomcast.net>
Message-ID: <f76dnSHHJKju4evfRVn-tg@comcast.com>
Source record: 19149

I know, I know, send it back to the factory or to a repair center. But that costs money, and I don't learn anything if I do that.

I have a couple of 0.7 to 3.0 Bausch & Lomb microscope pods that are messed up - - one white one that requires eye convergence for less than a foot away to superimpose the images, and a black one I just bought that is okay horizontally but has a vertical offset. They don't look like they were dropped or anything, but the left eye optical path seems different from the right eye path. It may be my imagination, but the right side of each instrument looks good.

I think just about any technician or engineer who needs to work with today's surface-mount technology needs a good zoom microscope, so there must be a lot of them around. I paid $15 for the black one today, complete with stand. Okay, I should be able to afford some repair expense to put this thing back in shape, but what's it going to go for after it's fixed - - $100? Can I get it repaired for $85? I don't think so. And I Google-searched all over for some hints as to how to adjust or repair this brand of microscope, but there's not a single post that I could find that was any help. I guess all the repair techs have signed a non-disclosure agreement or something.

Getting down to business, I opened up my black $15 microscope and found a series of mirrors in the section that allows interpupillary adjustment, and two movable lenses on each side in the zoom section. The mirrors all appear to be positioned by contact with machined surfaces on pivoting aluminum castings. It doesn't look like these can move around unless one breaks loose from the glyp they put around the edges of the contact areas. Looking into the empty eyepiece holes, the left eye sees a bright elongated spot (8 to 10% of aperture area) outside the aperture at about 10:00 at all zoom settings that is not present in the right eyepiece hole - - looks like a sneak path or a chip out of a mirror. The image offset of the left when eyepieces are in place is about 1/6 of a field diameter low compared to the right, and could be converged with eyesight set for 6 ft away, if the vertical offset were not present. This offset is exactly the same at all magnifications. The white microscope behaves exactly the same at all magnifications, also.

In the zoom section, turning the zoom control rotates a pair of cam shafts grooved for pins that drive Nylon pads along guides. Each lens is fastened to its Nylon pad by a couple of screws, and it appears possible to adjust lens tilt by loosening the screws a bit. I have resisted the temptation to see what happens when the screws are loosened, but is this the only adjustment for optical convergence we have? It looks pretty sloppy and difficult to control.

So have any of you dug into your microscope and figured out how to fix it? Do any of you with B&L training care to guide an old EE to make something good out of the junk he finds at a flea market?

Thanks for all your help,

Chuck, w6pkp

Hank -

The HBR receiver is a design by Ted Crosby (W6TC - sk) featured in a series
of QST articles from 1957 to 1969 and in The Radio Handbook, 17th Edition.

K5BCQ has entire web sites dedicated to these receivers!
http://www.qsl.net/k5bcq/HBR/hbr.html

Happy reading !

Tom Dailey's (WA&#65533;EAJ) story is interesting -- that we live in a small world.

The HBR series of receivers (8, 11, 13, 16, & even an 18 [# of tubes])
were originally designed by Ted Crosby - W6TC SK, back in the early 60's.
The original articles appeared in QST of 1963, and many of these EXCELLENT
receivers were homebrewed by amateurs throughout the country and the world.
A testament to their quality is reflected in the fact that they're still
being built, restored, and used. Although mine is not very pretty, it works
FB, and I regularly use it on Straight Key Night with a restored Heathkit
AT-1 transmitter (and the original straight key that I bought at B-A in
1959, for $2.95). It hears as well, or better than a Kenwood TS-430S or
IC-706 MKII/G.

Kees asked for HBR stories, so I sent him this one - thought your KAR readers might enjoy reading it as well. I encourage all to visit the website, and if you're interested in putting one of these critters together, you can still find all the parts. I have all of the QST articles, "HBR Notes" (construction hints), & original spec sheets on the tuning capacitor and IF cans. Anybody who might need copies would only have to pay for the copy paper and postage, but most all the info is on the website. ZUT de WA&#65533;EAJ AR

Hi Kees,

My HBR-11 came to me via an ordinary flea market in Denver. It was bought, along with several other pieces of "junque" from a seller, by KG&#65533;HS (Carl) out here. After a few weeks, Carl asked me to look at "this thing", as it was missing a tube, and had no markings as to what it was. Finally, he just

gave it to me, as he felt he'd never get around to messing with it.

I kept it under the bench for about 6 months, until one day I noticed the slipped Dymo label, under the lip of the cabinet, saying "HBR-11". I had figured out by this time, that HBR meant "Home Brew Receiver", but still didn't know much about it.

About that time, I received yet another complimentary copy of Ham Radio Trader, which was still being printed back then. In it, I found an ad by Charlie Brenner (WB9GJW) for an "HBR-16". Figuring it had to be a cousin of the "11", I emailed him. Charlie was WONDERFUL enough to send me: the ORIGINAL QST articles, a copy of "HBR Notes" (original version), A Full schematic, and copies of the ORIGINAL cut-sheets of the tuning capacitor, & the J.W. Miller I-F cans. Armed with this info, I determined the missing tube, and brought it up s-l-o-w-l-y with my variac... Voila'... NOISE! After repairing about 14 different problems, mostly solder joints, 2 tubes, and loose hardware, I aligned it with an HP-606 (one of the few that will do a 100 kc signal), and it was terrific. I should mention, that all I had was the 40m coil-set.

About a month later, I found another piece of Dymo tape under the wiring, and it read "WA&#65533;LJO". I looked the call up in an old callbook, and found that it belonged to Everett Huizinga - listed in Denver, CO. (HEY! That's where I LIVE!) I looked up the name in a Denver phone directory, and sure enough, there was still a Huizinga at the old address. After attempting to explain why a total stranger was calling her about an old radio, the lady ultimately informed me "Oh my, that's my son... I think he was a teenager when he built that old radio!". She gave my number to Everett (who now lived in Golden, CO - about 10 miles from me), and we spoke on the phone, finally promising to try to run into each other at the next hamfest.

It gets better...

At the Jefferson County hamfest, I was walking up to the front door, and I saw my friend Carl, with another guy. Carl says "Hey, you wanna' meet the guy who built that receiver?"... I said "Sure!". We spoke, and it came to light that Carl actually WORKED WITH EVERETT! Imagine that... you buy an old radio at a "civilian" flea market, and it turns out that a guy you work with, is the guy who built it, back in 1965!. Everett and I spoke, and he said to come over to his house later... I did.

Arriving at the house, Everett came out of his old garage bearing a small cardboard box... it still had the "ALLIED RADIO" label on it, postmarked 1965. Inside was the treasure... the coil set for 20m, and 2 of the 3 coils for 80m, along with several BRAND NEW National 5-pin coil forms. I've just found some No. 26 wire, and cut down an old 100 mmfd APC variable to 55 mmfd, so will be winding the last coil this weekend.

So, how's that for a story. The amazing circular world of Ham Radio, and how Ted Crosby lives on.

Tom Dailey

Bear in mind that the '2313 is obsolete, and has been replaced by the
Tiny2313 - cheaper, faster and with lots more stuff on the chip. They are
pin-compatible.

Many years ago (like, 20) I bought many 24" x 24" sheets of
single-sided PCB that I've been using to homebrew dead-bug style and
for other activities like soldering together little shielded boxes.
Probably mail-order from Fair Radio.I'm sure I paid very little for the
stuff at the time, probably a few bucks a sheet. Now my stash is
almost gone. Anyone care to recommend a good cheap supplier for
similar single-sided PCB? I'm not picky as to phenolic vs glass-epoxy
or whatever, I just need a good ground plane. Big pieces are good but
I can live with little pieces too.

The stuff I got 20 years ago was, for some reason, pre-tinned. (Maybe
this is why it was so cheap?). That was nice because I don't have to
clean off my dirty fingerprints when coming back to a project after a
few weeks or a few years :-). Pre-tinned is a big plus.

>Currently, they are used to generate high voltage for ion air
>purifiers (ozone), that are supposed to make the air safer to breathe.

Well, there's a distinction to be made between "negative ion generators" and "ozonators". The former tend to operate at significantly lower voltages, and aren't intended to create ozone (O3) although they may produce a small amount as a side effect. Their primary output is negative ions, which some people feel make the air more pleasant to breathe, and which definitely have the effect of causing pollutant particles in the air to precipitate out onto filters and onto every nearby surface.

I used to run a negative-ion generator in a commercial office space located right under the Los Angeles Airport approach pattern. Lots of stinky jet-fuel fumes and soot in the air outside. It definitely made the air in the office more breathable. It also made a horrendous mess of the walls and ceiling... after a month of operation I could see a "shadow" on the wall if I moved a calendar or poster, due to all of the soot and gunk which had precipitated out of the air. I understand that after I left the company, they had to repaint the office to get rid of the stained appearance.

Ozone generators are another matter entirely... higher voltage, more corona effect (or, they use a high-intensity shortwave UV lamp to create a similar effect by different means). I hate these things... can't stay in a room with one for more than a couple of minutes before my eyes start to burn and my lungs to ache. Why anyone would wish to generate a free-radical-producing government-listed airborne pollutant in their living space is beyond me!

Those piezeotransformer gadgets sound pretty neat, although I haven't played with one myself.

Does it come with a programmer? If not, you will have to buy or make one.
The SP12 programmer is very simple, I've used it for years:

http://www.xs4all.nl/~sbolt/e-spider_prog.html

I'd also get a few spare 2313 chips.

Try a Google search for CRT suppliers. Can't recall the name of the one I found, but there were a couple that are able to cross reference the numbers and can tell you which of the two is actually the CRT number.

Hello Tim,

See if there is a PCB manufacturer within resonable driving distance and ask for scraps. That's how I got a huge stash decades ago. Single and double sided, the good stuff (FR4). But it has to be picked up, in my case they wouldn't have gone through the trouble of packaging and mailing it. Basically it had to be no more effort on their part than a walk to the dumpster would have been.

Mine weren't tinned though. Also, I am not sure if constantly touching a pre-tinned board during experiments would be too healthy.

Regards, Joerg

Hello Tim,

Just one more thought: I use "living-bug" arrangements almost exclusively. Every once in a while I cut up some strips so they fit the most popular "underbellies" of chips. Then I glue the strips onto the large panel and the chips on top of the strips in a rider's fashion. Ground connection can be achieved by slightly bending down a pin, the rest gets wired up Sauerkraut style like usual. When stray capacitance is critical I take washed wood strips instead of copper clad. Makes for a really nice excuse to eat another Haagen Dasz.

This avoids having to think in reverse pinout and it often looks nicer, too. Plus you can still see the "CD4007" on the chip.

Or you can just bend all but the ground pins outward from the base of
the chip (e.g., www.speakeasy.net/
~jmiles1/ke5fx/492ap/large/close1.jpg). The pins won't break if you
don't flex them more than once or twice.

Sometimes I'll use a drop of cynaoacrylate adhesive to hold the chip
into place if there are few or no grounded pins, but it's rarely
necessary.

This also works for SOICs and even TSSOPs, as long as you don't bend the
pins more than once.

I wish I knew how this was done, but I don't. I DO know that the
company I used to work for once sent out their scope to be realigned
to a local camera repair shop. They apparently had some kind of laser
alignment system which helped this process.

You might try calling such a place just to get an idea of cost.

I've just posted a couple of QST Technical Correspondence items to my web site. Although published over 20 years ago, they're still relevant and might be of interest to some of the readers of this group. They are:

"On Solid-State PA Matching Networks" - An important characteristic of matching networks for class C solid state amplifiers, which doesn't seem to be well known even today.

"Choosing Wire Size for Toroidal Inductors" - Measurements showing that it doesn't make much difference. But people are still asking.

Both are at http://eznec.com/Amateur/Articles/.

The L network inductor in "On Solid-State PA Matching Networks" Fig. 1 should be 0.5 uH, not 0.5 mH. The correction I had penciled in 20 years ago was too light to reproduce and I hadn't noticed that it didn't show up. I've uploaded a corrected copy.

Thanks to John, KD5YI, for spotting the error.

Ebay might be good as someone else suggested. The best bet
for low CO$T material is to sweet-talk a PCB maker for left-
overs...if one is in your neighborhood. I've gotten fairly
good prices from www.circuitspecialists.com on double-sided
stock (comes in protective plastic envelope).

>The stuff I got 20 years ago was, for some reason, pre-tinned. (Maybe
>this is why it was so cheap?). That was nice because I don't have to
>clean off my dirty fingerprints when coming back to a project after a
>few weeks or a few years :-). Pre-tinned is a big plus.

Cleaning OLD PCB stock the "green" way -

Sprinkle any kind of table salt on the PCB stock, then take
half a lemon and rub it on the salt. Most of the blackened
oxide will disappear!

I tried that late last year on some 4" x 8" double-sided
phenolic substrate PCB stock after seeing all those "green"
site remarks that I didn't really believe. It WORKS! :-)
Those pieces had been sitting in the back of the workshop
for about 35 years.

I did "cheat" a bit. Have a year-round producing lemon
tree and my wife had some coarse salt left over from a
canning experiment. Zero cost trial...lemons at the
markets can run 50 cents each. The residue can easily
wash down the sink, don't need any gloves, nothing toxic.
Result is easily solderable although for best appearance,
some cleaning with a bleach-containing kitchen cleanser
will make it shiny and spotless.

Hello, i need a little, low power (about 500 mA) step up converter from 12 v dc to 24 v dc to operate correctly a 4 ways coaxial switch.
I have found project on the net, but i wonder if there is a ready, little, not ott expensive kit or ready-to-go-module to obtain this 24-26 v dc voltage from 12 (13,8) dc volt input.

Thank you,
73 de Riccardo IK5WQO

I think you might find a "wall-wart" power supply for a computer printer
to do the job.

You can find these in voltages like 24-28v @ 1 amp for maybe $10 new in
the US. Of course ours are 120v but I imagine you have the 240v types
available over there in I-land.

They are available. There are some for mobile police computers for example.
Also look for a 12 to 12 volt with isolated 12 volt output. You can use
the output in series
with the input to get the 24 volt. And a 12 to 8 or so may be OK as many
relays
will work with less than the full 24 volts.

Good luck.

Don't know about "page cannot be displayed" message but when I checked
the BAMA
site recently they had removed all HP material.

KEMO Electronics (germany) make these items. They have an interesting range of small modules with various functions. Have a look at their web page:

http://www.kemo-electronic.com/en/module/m029/index.htm

They are wholesale only, but have distributors around the planet.

There were some legal issues, but the BAMA maintainer was able to work through them with Agilent. The HP content is back up, as of a few days ago.

Supposedly there is an effort under way at Agilent to gather and distribute .PDF manuals directly.

Apart from that, it appears that a ham in Israel has posted a link to the 8555A YIG connection specs as part of an auction for one of the YIGs in question:

http://cgi.ebay.com/ws/eBayISAPI.dll?ViewItem&item=7512226957

I have no affiliation with this seller, etc., etc.

They are supposed to be putting it back after Agilent changed their
policy on out of print materials.

2252. VHF TX/RX switch w/ pin diodes

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-05-05 05:44:16 UTC
From: Bernard <bernard.debbasch_removethis_@mail.com>
Message-ID: <Roiee.10101$tQ.3258@fed1read06>
Source record: 19185

I am trying to design a solid state TX/RX switch for VHF (2-meter).

```
DC (when TX)
|
| pin diode
TX------->|---------- Antenna
|
delay line
|
|-------- RX
V (pin diode)
GND
```

(I am not good at ASCII drwaings !)

My problem is the design of the 1/4 wave line that allows the RX input to be grounded while showing an open circuit at the antenna. One possible implementation would be a length of coax but at VHF frequencies that will be messy. Commercial equipments just use an LC circuit. I am looking for a pointer to the design of this cicuit.

Thanks,
Bernard

Why is that? Lead? I thought that paint with lead in it was a lot
worse.

Back in the early '70s I got some prototype boards from a company that made aircraft receivers. They used four push-in pins, one for each lead of the four corners of the IC. Two of these are usually power and ground, pins 7 or 8 and 14 or 16. These four hold the chip up off the board, and the other pins are wired spaghetti style, which I presume is the same as your sauerkraut style.

Speaking of this.. Last Sunday at our monthly compouter club meeting someone donated a homemade S-100 system to the consignment table, but no one bought it, so it ended up on the freebies table later, probably then into the trash later. It had a chassis and box pop riveted together, and the S-100 bus was all wire wrapped. A lotta love and time went into building that way back in the late '70s.

You don't need an excuse. We give you permission. ;-)

BTW, you can go to Michaels or other hobby/crafts store and buy a whole
handful of ice scream sticks for a couple bucks. You don't have to wash
'em, then. :-P

Every year the Engineering Club has a model bridge building contest.
They make them out of ice scream sticks. They support the ends of the
bridge on some bricks and suspend a bucket from the middle. Then fill
the bucket with sand until CRACK! the bridge crumples. Pretty neat!

You could come on over afterward and get some free slightly used ice
scream sticks. :-)

I don't know what commercial designs use, but you can simulate a 50 ohm quarter wavelength line with a lowpass pi network (shunt C, series L, shunt C). The reactance of each component should be equal to the Z0 of the "line" (e.g., 50 ohms). This will behave just like a quarter wavelength line at the design frequency, and will be a good approximation over a typical amateur band.

I've amazed a few people when we go out to eat lunch. I take a tarnished golden dollar and put it in the lemon from a drink, or catsup works just as well. Less than a minute later, it's nice and shiny again. The vinegar or citric acid reduces all that tarnish to invisible. Some say the carbonic acid in the fizz in cola will do it, too, but I haven't tried it. Check it out sometime when you're into impressing your friends.

This may be slight overkill (they claim it's good for 100W) but it's
inexpensive:

www.oatleyelectronics.com/kits/k168.html

Alternatively, you could put together something quite simple using
an MC34063A (try Google) - easy to use, readily available.

I'm relatively new to this--pardon any vernacular errors. I've a 50mW veronica transmitter that I'm using around the house and yard. 9/12V DC power source. It currently has two flexible wire leads serving as the antenna and ground--each is 70cm in length and is directly soldered to the PCB. I usually coil them up to keep the range at a minimum.

Is there anything I can do to change the existing antenna setup? I'd like to be able to switch antennas to attain different coverages. I was told the impedance on such a unit is different than that of common connectors (BNC, F, etc). Is there any way to change this configuration to accept a whip antenna or a rubber duck antenna? I tried wrapping the existing wires around rabbit ears arranged vertically which seemed to give me an option for increased range.

Thanks.

Thanks this helps. I went into the wrong track because I ignored the shunt C
at the antenna point. Looking at it as a pi network is definitly helping
(not that I know the formula in top of my head, but I will find it !).

Now, the next problem will be to test the efficiency/tuning of the network.
I will need to correctly evaluate the value of the equivalent C's a the
antenna point and at the grounded diode point...

Thanks again,
Bernard

I'm guessing here.
It seems to me that if you have 140cm total antenna fed at the middle,
then you have a full size dipole (or close enough) at the FM-BC band.
That further suggests a 75 ohm output impedance.

It would take some work to match a rubber-duck antenna - and it wouldn't
be very efficient. However, you should be able to use a whip of about
70cm and not suffer too much for lack of the ground plane.

If increased range is the goal then 75-ohm cable to an outdoor antenna
(dipole, etc) would seem to be ideal. All would need to be done within
the regulations of your country, of course. :)

There's zillions of folks using the Veronica gear...keep asking around
and I'm sure you'll find something more definitive than my guesswork.

My 2c,

Bill

Yes Bill.
It sounds like that is serving as a dipole.
I too would strongly suspect that is a 75 ohm BALANCED output.
You should be able to remove the wires which are serving as the "dipole" and run them to a 1:1 balun and the other side of the balun to a 50-75 ohm unbalanced antenna. Or, to the input of a FM power amp....

Warmest regards,
John

It's a PLL that locks a Tek 492AP spectrum analyzer to an external 10 MHz GPS reference. The box contains an x100 prescaler, x10 prescaler, a phase/frequency detector made from two halves of a 74LS74, and a slow loop filter made from an LF356 opamp. There's also a relay that switches the correction signal in and out of the circuit based on whether the GPS reference is connected.

The 494 and 494A had the reflock assembly built in, but the 492A didn't. So I added it, along with a few other tweaks that bring it up to 494A-level functionality.

Lots of stuff in a very small box, without much room for component standoffs or other prototyping aids. I've built a ton of stuff that way, at frequencies up to and including 2 GHz. Wouldn't even consider any other assembly techniques for RF work at this point.

'Ground' has various implications when it comes to rf. If they tell you to attach it to a water pipe or ground rod then it may be a true dc ground. If they tell you to extend it just like the antenna side and not connect it to anything, then its an RF ground plane...which can be compared to rabbit ears, dipole, etc.

Is it balanced or not? Hard to guess.

Neat. Yes, sauerkraut style is similar to spaghetti style. No meat sauce
though ;-)

Oh, wire wrap. Most older computers were that way in the 70's when I was
at university. It caused a lot of grief but then I found out an upside.
As a student you are always short of money, looking for an opportunity
to make a buck. These old wire wrap graves still would have some life in
them but not enough for the institutes to warrant the huge service
contract expenses or $200/hour repairs. So they just sat there, dead.
Then I offered to repair them provided I could do it my way. Brought the
big solder iron and soldered the whole backplane which brought them back
to life. They actually ran more reliably then ever, some told me. Often
the pay wasn't money but a keg and pizza which was then immediately
consumed by me and some staff on the lawn in front of the place.

Have you tried the mirror site?

****
BAMA is now being mirrored! Through the generosity of Bob Duckworth,
AH7I and Ed Kujawski, a mirror of the BAMA ftp site is now available.
The mirror is a web site, so you will see the ftp archives when you
click on the mirror address below. You may find it helpful to look for
your manual using the BAMA site and then click on the mirror site,
navigate to the file that you want and download it. Please point your
browsers to http://bama.edebris.com

The main BAMA site is limited to ten simultaneous connections for
downloading. The new site allows 5 additional connections between 7AM
and 6PM Eastern, 15 between 6PM and 9PM and 50 between 9PM and 7AM.
That's right! Between 9PM and 7AM Eastern Time, there will be slots for
50 users on http:bama.edebris.com and 10 on http://bama.sbc.edu

I'm gathering from what you've posted that you don't have many design/analysis tools available. Have a look for "RFSim99"--a Google search should find it for you. It's freeware. It will let you make a model of many linear RF circuits quite easily and get a decent feel for what to expect in the way of performance. You can model a PIN diode quite reasonably as a low-value resistance when "on" and as a capacitance when "off". The data sheet(s) for your diode(s) should list reasonable values to use.

Then you can easily see what sort of isolation you'll get versus frequency, for example, and get an idea about the losses. If you have any question about losses in inductors, estimate their Q at the operating frequency and put in a resistor to account for that. Capacitors, at least decent RF caps, have low enough loss that it can usually be ignored.

RFSim99, in addition to the simulation stuff, has some "tools" accessible from pulldown menus that will design simple filters for you, calculate inductance, capacitance, frequency or reactance--enter two of those and see the other two--and some other useful RF things.

Hope this helps some!

Cheers,
Tom

If the output is really Unbalanced, and he fed an unbalanced ant of 50 ohms--nothing--as likely a 1.5:1 (75/50) match as not...

Or, depending on the type of ant he picks (75 ohm bal/unbal), and taking for granted the output of the rig is balanced--probably just a distortion of the radiation field of the ant (won't EXACTLY perform as modeled)...

Even if he feeds a bal ant of 200 ohms (folded dipole, and output is balanced, all he sees is a high (200/75) SWR, and distance is reduced...

But, hey, I am a newbie... that is only my best guess(s)...

Warmest regards,
John

That is why I mentioned "UnUn." It is taken for granted he will ask, or use
the correct one (Balun/UnUn)...

A balanced "supplies its own ground." A ground or "counterpoise" is NOT
required for the ant to work against...

Warmest regards,
John

2284. Stacking Big Wheel Antennas???

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-05-05 23:48:02 UTC
From: Dr Dave <wvdave1st@hotmail.com>
Message-ID: <Sgyee.31930$r81.29132@trnddc02>
Source record: 19067

Looking for some INFO on how to Stack Big Wheel Antennas ?

Operating Frequencies TX-421.250 to RX-439.250 ATV repeater.

Would like to feed with equal lengths of coax from one Power Splitters if possible.

I thing the stacking distance is around 16 inches.

And There is something about right hand circular and left hand circular For proper phase.

Thanks Dave

2285. Re: FM Tx antenna options

So then a dipole with one leg 5 times as long as the other would be a "balanced" antenna. I see.

Tell me, how is this "ground" "supplied"? What exactly is a "ground", say 50 feet up in the air?

Roy Lewallen, W7EL

Well, "di" = two, so in that sense, "dipole" would not necessarly be balanced--however, that is not what I expect when someone tells me they have a "dipole."

Although, quite well granted, it qualifies (my groundplane ant is a "dipole", but I think I would mislead if I stated that in some circles! (as it does have a few extra "legs" on one side.) However, it (the radials) could be viewed as one single conductor, in the sense a tophat might be a sheet, or a set of multiple wires, or the bottom cone of a "discone" composed of many "legs" as compared to one solid sheet of conductor...

Semantics: retarded person = mentally disabled = special needs = handicapped, etc... don't ya just love it!

"Gound" at 1000 ft in the air is a counterpoise (body of an aircraft, most likely what the neg lead of the power source is hooked to), could be one long wire to ground too--most likely in need of "tuning" to function optimally....

If I someone stuck a 1K resistor (or diode-anode towards +) between my chasis of the radio and the negative lead (probably best to bypass it with a cap at rf in question), the top of that 1K resistor (or cathode of diode) is "real ground"--in the sense of "time" being real... they "ground" every telephone pole now and then, because across distances "earth ground" is not "equal ground."

If your point is that "ground" is relative--I know a guy who claimed that of the whole universe....

That guys ground could well be the chasis (even though a 1k resistor!), or the other side of coil with its center at "ground", or not... etc.

But, those two wires he described are two wires of equal length, so, suggest themselves as a "conventional dipole", with nothing else to go on--I am willing to accept that...

I have been wrong before, is so this time--I learn something...

Warmest regards,
John

My intent was to spur some thought about the meaning of the terms you've
so liberally and seemingly authoritatively tossed about. These
"explanations" show that your understanding is, indeed, very muddled and
vague. I suggest you do a bit of study to gain a clearer grasp of these
concepts before you give too much advice about how to apply them.

Very nice package. Thanks for the tip ! I agree that this is the right way
to do what I am trying to do but I was not willing to invest time an money
on this. Luckily the price is right and the package seems to be very easy to
use (from the 5 minutes I played with).

==========
Printed circuit board scraps up to large pieces ,be it usually double sided
, are always available at ham radio flea markets in the various european
countries. I think I have stocked up for life ! From the larger bits you
can make neat enclosures.

Yes, I've been able to get it at the local "surplus" outlet for
thirty years, though I suppose at this point many a location no
longer has such a store.

They often have board that has been drilled, or shaped in a certain
design, clearly overrun or projects that got scrapped. If you
aren't actually etching the board, or if you only need small pieces,
these work fine and cost even less.

Because it's cheap, I've done things like use it for panels on projects.
Circuit board is a easier to work with than metal, yet the copper
provides shielding.

I've even pulled the copper off boards when I need it gone, though
that tends to be tedious. If it's just a small piece, I grind it
off.

Riccardo-

If you have a 12 volt inverter of any kind, you might look at the primary side of its circuit. If the transformer center tap is connected to 12 volts and it uses switching transistors to alternately connect the ends of a transformer winding to ground, then you can connect rectifiers from the ends of the transformer winding, to a filter capacitor for a plus 24 volt supply.

When one end is grounded, the center is still plus 12 volts, so the opposite end of the winding becomes plus 24.

Source record: 19078

One of the characteristics of the lowpass pi network Roy suggested is that it provides a DC path between input and output. (Well, it IS a lowpass, after all!) That characteristic can be a blessing at times, in that it lets you use the same DC bias current for both the TX path series PIN diode and the RX path shunt diode. But some other arrangement might benefit from DC isolation between the two nodes, and you can get that by changing to a highpass configuration. You have a choice of a couple of them using three parts: a PI configuration or a T configuration. In both, the shunt branches are inductors and the series branches are capacitors. So a PI gives you DC-grounded input and output nodes, and a T gives you DC-isolated nodes. And you can also use a T lowpass with series inductors and a shunt capacitor. In each case, all the Xls and Xcs are equal to the resistive reference impedance. In other words, for example, at 150MHz and in a 50 ohm system, C = 21.2pF and L = 53.1nH. Each of the four configurations (pi and T, lowpass and highpass) behaves at the design frequency essentially like a 1/4 wave transmission line.

Cheers,
Tom

If you send me a place where I can send you about 3 meg of files I will send
you a scan of the stacking from an old VHF handbook for a 2 meter version.
They recommend a 5/8 wavelength spacing. Also there is no right or left
hand circular for the wheel. It is all just plane horizontal.

I work for a PCB manufacturer. All scrap has to be accounted for, and is then sent for recycling (copper is costly). I've managed, over the last couple of years, to get hold of some pieces of scrap, but these are few and far between.

For cleaning boards, we use a sulfuric acid and pumice scrub. That last part should be doable at home (I certainly won't be messing with reagent grade sulfuric at home!). Maybe using previously mentioned lemon juice?

Basic white vinegar from the grocery store is a reasonably safe acid to work with. Cheap to experiment with different concentrations, and probably stronger than the lemon juice, certainly less expensive.

I've never found anything on blank circuit board that couldn't come
off with just a good scrubbing, so obviously there is no need for
heavy chemicals. I seem to recall using soap at some point, which
worked, and I will try the vinegar.

The real issue is that no matter how shiny you get the boards, unless
you coat them with something they will tarnish with time.

If "operate" does NOT mean "hold" (i.e., if you just need pulses of 24 volts)
then you can wire a capacitor to a switch such that the capacitor charges
to 12 volts and then ADDS to that same 12 volts to operate the relay.

True for most metals. Flux does a good job of removing the inevitable little bit of tarnish/oxidation.

I did not mention earlier that it is very important to throughly rinse off any acid, however mild, that you use.

There are ways to plate the copper with other metals less likely to tarnish or oxidize, such as silver, or even gold in critical applications.

Well, i need a stable 24 v dc voltage, not just a voltage peak to 24 and
back to 12.

Thank you,

Thanks Fred, but i would like the dc-dc inverter solution to be able to
operate the switch from any 12/13,8 vdc source.

That unit could run cooler or produce more output if the rectified secondary were stacked on the +12 input, so it had to produce only the additional voltage. Just cut the secondary turns almost in half.

Or better yet, just add a few turns past the point where the drains connect (which go up to almost twice the input supply voltage), and connect those points to the output through one diode, each. Eliminate the secondary, all together and raise the efficiency a bit more. But there should be a filter choke between the rectifiers and the output filter capacitor to average the slightly over voltage pulses with the zero volt spaces between them.

2309. HB projects in London

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-05-08 05:21:44 UTC
From: Bill Meara <meara.london@virgin.net>
Message-ID: <427E048D.49DC@virgin.net>
Source record: 19092

In the interest of stirring up more discussion, I thought I'd give an update on projects here at M0HBR (HomeBrewRadio).

-- Yesterday I put a new (old) 17 meter receiver into operation. It is a Doug Demaw "Barbados" single conversion superhet. I built one from scratch for 20 meters many years ago (see my web site for details). Somewhere along the line Dale, W4OP, sold me his version. I used that one briefly on 20 meters, but then it spent a lot of time on the shelf. Lately I've been looking for a dedicated RX for my HB 17 meter SSB TX (sharing the Drake 2-B with other transmitters involves too much cable plugging and unplugging at bandswitch time!). So Dale's RX was pressed into service. I widened the 5 Mhz ladder filter for SSB service by changing the caps. And I got some 23 Mhz crystals from JAN to make a VXO that would cover 17 meter phone. I use 2 crystals and can switch betwen them from the front panel. I worked Estonnia with yesterday.

-- It may be that I'm getting lazy, but continuing with the "let's make band switching easier" theme... I was getting tired of having to retune my balanced antenna tuner each time I went from 40 to 17. The circuit was so simple, I just decided to build another one, and make it a dedicated tuner for 17. It is the classic balanced tuner circuit -- I think it dates from the thirties: tank circuit link coupled to the TX, with the parallel feeders connected to the coil via small alligator clips. Now I can just go from band to band with the push of a button.

Upcoming projects:

-- I need to put my HW-30 on 2 meter AM. There is a very active VHF-am group here in the UK and I need to get on the air. I plan on using the lunchbox with a converter-to- Drake 2B for receive.

-- I need to match up my old Mate for the Mighty Midget RX with my 40 meter DSB transmitter. I have a 455 khz SSB filter for it, but I haven't figured out yet how to match the impedances and get it into the RX. Filtering currently being done -- poorly -- by one 455 khz IF can.

Source record: 19093
Body handling: HTML body converted to readable text

Decades have brought us moon landing, mars landings,masers, lasers, lets, fets, mosfets, computers, etc...

But the shape of radio equip. has remained virtually stagnant.

One "innovation" would be to just copy what the IBM clone has taught us.

Build a radio of "cards." Just like the computer, a standard case which you can plugin various power supplies, frontend board "cards", intermediate board "cards", buffer amp board "cards", IF board "cards", audio board "cards", xmitter board "cards", final amp board "cards", etc....

One radio case can/could virtually be any radio you can imagine.... new design in a frontend? Plug in a new front end "card", new audio offering? Plug in a new audio board "card."

Someone really should get off a dead duff somewhere and DO IT!!!!

Kinda makes ya wonder why not? Doesn't it?

Warmest regards,
John

Hi, all concerned:

I'm trying to revive my flagging interest in hamming in general.

If you have a homebrew and/or kit project, sitting around, send me a picture, its weight (for ground shipping estimate to 45251), and what you'd like to get, and maybe we can shake hands and do business.

Tubes or transistors -- doesn't matter.

TIA and

73, Dave, N3HE
Cincinnati OH

Jeez Dave, there's your problem staring you in the face. You've got too much money and are too lazy. Common instant gratification problem these days. If you want more pizazz in your hobby, do something different. Since we can't seem to get a good QSO going except for the one in a thousand, the "fun" lies in doing something else instead of buying a radio and talking. (Or worse, listening) Try melting some solder and getting some REAL enjoyment out of using a piece of gear you've brought to life yourself. The pleasure is never ending and the challenges are great.

For starters, there's the kit route, the Elecraft folks have a cool radio, and if you want a greater challenge, any of the homebrew sites from the CDG2000 to the PicaStar projects will do it (Google finds them both and more) and make you a radio that performs better than ANYTHING you can buy. Too bad the league didn't do either of them. Then too, you can make some homebrew test equipment that falls in the same category and honestly evaluate that new piece of gear. Might even interest you in a new hobby of real metrology. This "hobby" will carry you to the grave if you just give it half a chance. Line up a thousand "projects", and you can't die, there just isn't any time for it.

Regards
W4ZCB

Actually, sounds a lot more like the Elecraft K2. Nothing new with the approach. Better spent, would be the time and effort to improve the operational performance. In-band dynamic range could stand some improvement, and oscillator phase noise is an abomination both on RX and TX of most every radio out there. Someone COULD, if only he would. Too busy dreaming up defunct ideas.

Russ:

That is my point! Too many look at ham radio as "special" and "separate."

What I suggested was gov't, commercial and, yes, even CB in that suggestion.
I am just guessing, but you market to that wide a group and you are just
bound to sell a dozen--or two!

And, having the design so others can purchase rights (reasonably charged!)
to use "your case", then the innovation brought to the market by "the many
manufacturers" (and thousands of minds) gives your product real "SEX
APPEAL!"

Warmest regards,

John

There is a group for people building Paul Wade's 222 transverter at
Yahoo Groups:
http://groups.yahoo.com/group/222Club/

See Paul's website at http://www.w1ghz.org/222xvtr/222.htm

The transverter is designed to mate with the Yaesu 817, but it will
interface with any rig as long as you're careful not to exceed the
maximum power input to the transverter. I wouldn't call the transverter
"super high end" so if you want to use it for EME, you might need to add
some stuff to make it work in such demanding applications. However, for
casual contesting and operating, it should be more than sufficient! I
have the circuit board for it (it's TINY!) and will be building it after
I finish up my 10 GHz transverter project (hopefully before Field Day!!)

This may be the answer to your dreams. A SOFTWARE DEFINED RADIO!

http://www.flex-radio.com/

This radio is basically controlled by software. Selectivity not good
enough? A new program is written and distributed (the programs are
free!)...

New band authorized? New software is written to include the new band...

A new digital mode invented? Yup, new software is written to give the
radio that capability...

Well, if what I see coming on the horizon is what I think it is--American dominance in "innovation" is dying....

With China, India, etc. "coming online", even the American consumer will soon be of small importance... even our auto manufacturers will soon be selling more cars there, than to citizens here... as these countries continue to "harvest our bucks" and upgrade, soon we will not even be able to compete over the cost of oil--it will go where it is more important--manufacturing over-seas...

Tying the hands of ourselves with overly restrictive rules and regulations which hamper our ability to compete has been taxing too--some of these ideas can only be instituted over-seas--where they will soon see the idea of promoting innovation and forward progress is conductive to even their self-serving interests...

Not everyone sees salvation in a new regulation, law or restriction

But, we will see...

Warmest regards,

John

Intriguing idea, but how would this work with varying licensing
requirements on some of your proposed bands, maximum power
differences, as well as the "type acceptance" or certification
required for operation?

Would changing cards within such a unit count as a mod, presently only
allowed for licensed amateurs transmitting on amateur frequencies?

You are on the right track as far as getting marketable numbers, but
the rules are so different for the various bands you mention, I am not
sure that can be resolved, even if all of the technical issues can be.

Happy trails,

It would work like EVERYTHING else in the world works!!! <am I the only one realizing that>

You can buy a diesel truck if you want to--but can't drive it unless you are licenced. You can build/buy a car with a thousand-horsepower engine--but have to be careful how fast you go on highways... You can buy a handgun and use it to protect yourself--but suffer the wrath of "God" if you error... You can buy poison--but can't poison your neighbor... you can buy razor blades--but can't put them in the apples you handout at Halloween... you can buy gasoline--but can't use it to burn down anothers property... you can buy a car--but can't use it as a weapon and run down people on the street...

Yanno, they USED to teach this stuff in school!!!!

Warmest regards,
John

Your comments are interesting. In the late 1970s and early 1980s, the
amateur market did begin down this road.

Look at: The Heathkit SB-104(A) and the Yaesu FT-ONE. there were a number
of "lessons learned" from those experiences - but the "state of the art" has
also moved from "thru-hole" construction to surface mount.

This concept is not unique to amateur radio, network equipment manufacturers
have gone back and forth between "chassis based" equipment and "appliance"
at least 5 times over past 20 years. Each has their unique attributes,
advantages and disadvantages ....

Shucks, Harold, it's nice to read from you again.

I should have mentioned that I have a K2/100, an R2Pro, T2, AA0ZZ DDS vfo ... and some other things you mentioned. Wish I had 10% of too much money ~ ;o)

I'm looking for serious detritus, from others, which needs completion, modification, and so forth.

One thing I'd like to find is a homebrew QSD board, to use with the R2Pro downconverter and DDS vfo, and the I2PHD software.

Kind regards,

I've considered this sort of a radio before. There are a few problems, however:

First, there is a fundamental difference between digital systems and analog systems that prevents this sort of thing working with the success of a PC.

The basic difference is that with a digital system you either end up with a clean signal or a useless signal. In an analog system the character and purity of the signal must be carefully guarded, at least until you manage to digitize it. This means that there will be a much greater chance that adding a new card to the radio will degrade not only the function of the new card, but the function of all the other cards.

Second, the PC market is a huge one, with great advantages to be derived from common equipment and software, and much smaller advantages to be derived from commonality. This is the exact obverse of the radio market, including homebrew radios. To make a "card" radio would be to define a basic radio architecture, probably down to the IF frequency (or at least to the point of forcing you to match your IF and front end). While improvements could be made within this structure an independent experimenter couldn't play around with such things as direct-conversion, different IF schemes, etc., without extensive modification.

In this way the radio market is more like the market for computing devices as a whole. The PC market doesn't account for the most

processors sold, or even the most dollars of all computing devices. The largest segment of the market is in embedded computing devices ranging from things as visible and obvious as your PDA, through cell phones, and down to burglar alarms and TV remotes. Take apart a new home thermostat or TV remote and there's a good chance that you'll find a processor that implements most of its functionality in software -- but a very slim chance indeed that its PC compatible!

You can get a software defined radio. Front end, and pipe it into your computer, and there ya go! Ten Tec also manufactured the Pegasus a few years back, close to what you are thinking of.

Personally, I don't think that the PC computer paradigm is any way to go. It's just how PC's evolved. Despite years of progress, plug and play is not universal, and just another PC promise.

I hope you are kidding, John. That is the absolutely worst part of the PC paradigm. Thousands of perfectly good electronics thrown out, often made obsolete due to software that is bloated and poorly written (mostly OS software. At least old radios are still useable

> I would think there must be some EXCELLENT argument/reasoning serving as a
> road block, or else, others are simply going to pass us by...

The PC paradigm is a poor one, and not to be emulated. PC's will finally be mature when we don't have to replace them on almost a yearly basis. At that point, software writers will be able to write good software.

I use Free Agent. It doesn't do filtering, but as I said, I turn on my
mental filter that says, "When you see a post by 'John Smith'", ignore
it. I used the same filter for "Fractenna." Works fine.

The Ten Tec Pegasus is very much alive . It is now called Jupiter (the
Pegasus with 'knobbed' front panel and a display and a nice enclosure like
other traditionally looking radios)

I do tend to be that way. And because of the couple of negative comments about my posting I've thought it over a fair amount to see if, on reflection, I think it was out of line.

But I don't think so, unless I mininterpreted what "John Smith" said. What he seemed to be saying is that he has this great idea, and the only reason it's not being impelemented is that *the other people* are too lazy to do it.

As one of the "other people", I find it kind of insulting. Do you really think his is a valid point of view, that everyone else should jump up and implement his great idea, while this anonymous person's job is to tell us what we should do?

I really do think that a caustic comment was appropriate.

AHA! Well, the recommendation still goes. You obviously were not
sufficiently challenged by the kit route, time to tackle something more
complex. Suppose you could say in a QSO (with as much false modesty as
possible) "Rig here is homebrew" even with a kit, however, would suggest
that the pride that goes with it is proportional to the time and effort
involved in bringing the project to fruition .

Now what else you gonna do with these lengthening days that would bring as
much enjoyment? Surely not "Receiving you on a completely refurbished and
freshly oiled gear train on this R-388 and model 28". Particularly when in
all liklihood, the Frau, upon hearing the above would tie 2 and 2 together
and realize that was where the oil stains on the Persian had come from.

He gave the impression of being someone who'd been here before,
though at least it wasn't cross-posted to the UK newsgroup.

It just struck me as "well what's it doing here?". This newsgroup
isn't about commercial equipment, though we seem to have a slow
slide to where such things do appear here. Yet the poster seemed
to be talking about commercial equipment, and whether or not
that was the point, making your own equipment shouldn't be quite
about building a copy of something someone else built.

Had he posted in rec.radio.amateur.equipment I think perhaps
the tone of the response should be different. But here, at
the very least it should be a discussion of modularization rather
than subject header that is bound to alienate, and an expectation
of how things should be.

The talk of modularization, which seems better fitted to radio
than "plug in boards", has been discussed quite a bit over the years.
But of course, rather than some universal system (which has had
some articles in the ham magazines) the focus has been on breaking

things down to smaller portions so you can experiment, or you can change things without having to change everything. And yes, solid state devices, because of their small size, low price and even function allows a better implementation. When you can switch with DC it is much easier to do modularization than if you have to have everything hanging off a bandswitch.

Quite agree, particularly since the "idea" was so poorly thought out to begin with. Personally, I'd be glad to own a box that was seriously better in performance that any current offering, even if it were spread all over the table and housed in a cardboard box. I'd then be wishing all my neighbors had one as well so I wouldn't be stuck with THEIR radios shortcomings. Even be willing to buy the things for the two closest ones.

To make a positive posting about why the "board" receiver doesn't exist. . . First, I consider my PC. While my very first PC had a bunch of cards, my current one has none except the RAM. The video adapter, Ethernet capability, sound system, modem, serial, parallel, and USB ports are all on a single board, built in.

Why? Simple -- it's cheaper.

I worked at Tektronix for many years. During that time, Tek made both portable scopes and laboratory scopes, the latter having a mainframe and plug in modules. For a given configuration with the same features, the lab scope was always considerably more expensive than the equivalent portable. Why? Well, the lab scope was always overdesigned for any particular job. The bandwidth of the interface had to handle the highest frequency plugin. The power supplies had to handle the highest current plugins, in any combination -- enough current at 5 volts for a digital analyzer plugin, enough higher supply voltage current for a spectrum analyzer plugin, and so forth. There had to be enough connector pins and supporting circuitry to handle all possible controls on all possible plugins. No single configuration ever used more than a fraction of the built-in mainframe capability. While the portable scope's stages could have optimal gain, in the lab scopes, the signals always had to be normalized to the levels specified for the interface. This often required an extra stage or two for each of the signals being passed (vertical, Z axis, horizontal, and many controls). Power supplies had to be decoupled in each plugin at the interface. And finally, good quality, reliable connectors are much more difficult to find, much more expensive to buy than you'd think -- and even so, they can easily be the least reliable components in the system.

Then there's the problem of trying to predict what would be developed in the future when you design the mainframe, so you can build in the necessary interface circuitry. And every new plugin (I've designed them) has to be compatible with every tweak and trick used by all plugins in the past which it might be used with.

The fact is that hams, for sure, wouldn't pay all the extra money a well designed plug in system would cost. Of course, I might be wrong -- anyone who thinks so (one particular person comes to mind) should get busy designing and developing one. Perhaps there's a fortune to be made. Certainly there's a market for a much simpler plug in system with much less versatility than the oscilloscope system I described, as a few manufacturers have shown. The question is, how far can this be taken before the market dries up due to the increased cost?

Yes, I use my filter too--and support and expect others to use them as they see fit... I certainly do mine!!! I can help if some are having difficulty; I support filtering and have an understanding how to apply them...

However, the very vocal ones--I am always left wondering if they really are remarking about filtering their own content--or their wish to filter the content of others (and, for what purpose would they do this?)... if that goes on too far (controlling others), yanno, it leads to attempted thought control--a guy wrote a book about that--George Orwell... Was that in 1984, or was that about 1984? .. anyway, if you ask me--he was more a prophet, some have already grown to accept what he (we?) feared...

Warmest regards,
John

Hmmm, I thought it "right in line."

If such equip. was adopted, then just as with computers, you could buy/cut/etch a "card" with the expectation it could be inserted right into the bus of that radio and function, taking on responsibilities--for say an audio amp (just as that EXACT capability exists with a computer bus)....

Indeed, this idea does NOT bypass homebrewers, it encourages them and provides them MUCH more opportunity to participate in constructing their own equip.... I see it as EMPOWERING homebrewers--far from the opposite!!!

Indeed, if some were as gifted as all that, they need only buy the case and some foil boards/components--when they emerged from the basement--I'd expect to see a radio of their OWN design in their hands!!!

Warmest regards,
John

"... before we are all doomed". The only way doom happens is if you don't do your part in averting that projection. Or are you saying the future is hopeless?

So, what are you doing to be part of the "solution" rather than being the "profit of bad things to come?"

How many hours over the past year have you worked with middle or high schools students volunteering your time? Donating materials, time or money for educational programs targeted for the audience that will make a difference?

As George S. Kaufman wrote about money and knowledge in the 1930s - "You Can't Take it with You".

Tim:

I agree, there is a "divergence" of most other devices, with radio in the "lag."

The technology of the 1920's-1930's has been bypassed--we are too late to halt progress at that point--the question is--do we wish to halt radio technology at this point--realizing--we will NOT halt those around us... in the end, leaving us, really, no choice anyway...

Name a large business still using calculators and slide rules, as opposed to the computer, and you will point out that what I am stating is a fallacy...

Warmest regards,

John

| >
| > John
|

| I've considered this sort of a radio before. There are a few problems,
| however:
|
| First, there is a fundamental difference between digital systems and
| analog systems that prevents this sort of thing working with the success
| of a PC.
|
| The basic difference is that with a digital system you either end up
| with a clean signal or a useless signal. In an analog system the
| character and purity of the signal must be carefully guarded, at least
| until you manage to digitize it. This means that there will be a much
| greater chance that adding a new card to the radio will degrade not only
| the function of the new card, but the function of all the other cards.
|
| Second, the PC market is a huge one, with great advantages to be derived
| from common equipment and software, and much smaller advantages to be
| derived from commonality. This is the exact obverse of the radio
| market, including homebrew radios. To make a "card" radio would be to
| define a basic radio architecture, probably down to the IF frequency (or
| at least to the point of forcing you to match your IF and front end).
| While improvements could be made within this structure an independent
| experimenter couldn't play around with such things as direct-conversion,
| different IF schemes, etc., without extensive modification.
|
| In this way the radio market is more like the market for computing
| devices as a whole. The PC market doesn't account for the most
| processors sold, or even the most dollars of all computing devices. The
| largest segment of the market is in embedded computing devices ranging
| from things as visible and obvious as your PDA, through cell phones, and
| down to burglar alarms and TV remotes. Take apart a new home thermostat
| or TV remote and there's a good chance that you'll find a processor that
| implements most of its functionality in software -- but a very slim
| chance indeed that its PC compatible!

Exactly my point....

We break into two groups of thought here...

Halt at this point, and lay all plans on that halting (and, if ALL the
others don't agree--be bypassed anyway)...

Or, stay with the pack, realizing if that day ever comes (technology ceases
to innovate/obsolete)--we will regret it...

Progress, obsolete equip., is the most desirable thing I can imagine! It is
a given, not all will agree... Indeed, at 52 years of age, my place in the
"scope of the world" is becomming smaller--it only gets worse from now on--I
am not ready to quit and attempt to force others to that "quitting" with
me...

When the "Dick Tracy Wrist Radio" is finally designed and
implemented--perhaps there will be a "death of homebrewers" (I myself am NOT
much of a 'watchbuilder')--but until then we can have fun!

Warmest regards,
John

As others have (I think) pointed out, there are some very valid
technical and regulatory problems which might make this approach less
than popular.

Here in the U.S., at least, transmitters in most of the radio services
have to be "certificated" (previously "type accepted") by their
manufacturer, demonstrating that they comply with the operational and
emissions rules for that service. In these services, almost any
physical modification of the radio will invalidate the certification,
and make it technically illegal to use it to transmit. Modifications
which don't violate the certification can only be made by technicians
or organizations with a specific license, and (I believe) may require
a significant amount of re-testing to demonstrate that the radio still
meets the requirements.

The FCC rules don't provide for the arbitrary swapping around of radio
cards in such transmitters.

Also, there's a tradeoff between modularity, and cost/performance.
The more modular a radio (or computer) is, the greater the number of
gozintas and comesoutas (i.e. signal connectors, busses, etc.). These
add cost, they decrease reliability (compared to a soldered
connection), and they limit the degree to which one can take advantage
of increasing degrees of device integration at the chip level.

The highly-modular PC infrastructure has gotten to where it is, in
terms of price and flexibility, because of the extremely large number
of units produced - there's a lot of "economy of scale". This is due
in large part to the fact that consumer, business, and industrial
applications can all use the same architectures. People have also
been extremely eager to take advantage of higher-performance
components and have been willing to accept relatively short product

lifetimes as a result... and this increases the demand for a "change out part of the system and keep the rest" solution which demands modularity.

I don't think that the same environment exists for radios. Commercial and public-safety radios have a long lifetime, they have the need for physical ruggedness which may discourage the use of a "plug-in" architecture with lots of connectors that can shake loose, they're rather cost-sensitive, and for regulatory reasons they probably cannot adopt a "Users may change out components" architecture.

In these radio services, a "You buy it, and it never changes" shrink-wrapped monolithic radio design simply makes more business and economic sense.

Things may become a bit more friendly in this regard, at least for base stations, with the newer "software defined radio" architectures. However, in commercial and business services, the FCC insists that the systems be designed and built in a way which prevents users from making arbitrary changes to the configuration which could violate regulations. One example of this is the Atheros 802.11a/b/c wireless radio cards... their behavior is very strongly defined by their firmware, and the vendor says that they *cannot* release the firmware or low-level drivers in source-code form for fear of violating the FCC's software-radio rules.

Frankly, I think that the amateur radio service is probably one of the few services (and perhaps the only one) in which a general-purpose "radio card plug-in" architecture or system could be generally useful, and the resulting radios would probably be significantly more expensive than monolithic-board or proprietary-bus radios of similar capabilities.

Due to the limited size of this market (compared to business and public safety) I doubt that you'll see the big manufacturers invest the time and money required to develop and promote and market such an architecture. No sense in their doing so. Without the leverage of being able to use the same technology in other radio services, it's be a big investment for no return.

>Indeed, if some were as gifted as all that, they need only buy the case and
>some foil boards/components--when they emerged from the basement--I'd expect
>to see a radio of their OWN design in their hands!!!

And there, I think, you've defined the only market to which such an architecture would be strongly attractive - hobbyists.

There might be enough of a community there to support the development of such an architecture, just as there are communities supporting the GNU software radio, the RockMite, and other specialized radios.

Feel free to propose a design, John Smith! If it's as overwhelmingly good an idea as you seem to think, maybe it'll take over the world by

storm!

In short, John, I don't think it's fair to say that there has been "no progress". Rather, I'd say that things haven't gone in the direction you suggest, because your solution is one which solves a problem which most people don't feel is worth solving, and comes with a cost that most people don't care to pay.

Is it "open source" and do they encourage others to innovate off their
platform, if not, totally different idea then what I present/envision...
can you buy just a case and basic powersupply?

Warmest regards,
John

Well, things have not gone as one would expect...
And, they may well be due to rules, regulations, and mindsets... and,
specifically, ones generated from an "American mindset."
Now, there is the "rest of the world" as we move to "globalization" these
ideas here will hardly set the course--I have afraid our part will be more
of passenger, as opposed to a captain... the best I can see is, using our
"paddle" we are able to affect a slight course change in our favor...

If one of your arguments is, don't propose any ideas until you have a
complete working design--I see that as more an answer to my original
observation... progress remains slow-to-halted, that simply being one of
the contributing factors...

If you seek to give a list of "why it can't work", that is helpful, but,
bear in mind, I was looking more for a list of "why it can."

Warmest regards,
John

I don't know you "Mr. Smith" or have any bone to pick with you but I use filters to avoid what I find as either offensive or provocative. I invoke enough cat-fights of my own on Usenet and don't need to be drawn into others. Some posters have a tendency to attract fire, and I have a weakness to jump in sometimes. I'd really rather just avoid it. My sanity and blood-pressure will be the better. So, thats why I filter out the provocateurs if I feel that strongly.

My filters don't prevent anyone from saying what they want to say. But historically, some posters can be counted upon to say what I'd rather not have to read and wind up being diverted from the topic or grappling to bite my tongue, etc. Its easier just to filter them away. Call me Ostrich-Man. Its my means of finding satisfaction with Usenet.

For my part, feel free to choose to speak. And respect my freedom to choose whether or not to listen.

Ohhh, well, you are correct. I am rather blind to "politics" and come from areas where new thought, conversation--indeed, even argument and debate are encouraged and viewed as "good things."

While not attempting to invoke "havoc", "discord" and "chaos", I view the manner in which topics are handled as being the deciding factor--foul language, character assassinations and promoting outwardly dangerous evils which threaten the moral fabric of society are as disgusting to me as the next guy...

If the material is just gauged on whether it provokes debate, argument and thought--and if the measure of this is simply how many posts are invoked as responses--with the desirable number set as one or NONE--then further delays in progress should be expected...

A silent discussion is beneficial to no one... and certainly don't view such as desirable!

Warmest regards,
John

wellllll, I think there is another reason that it hasn't been
implemented. It is one of those ideas that sound kinda good, but would
end up creating more problems than it would solve.

> As one of the "other people", I find it kind of insulting. Do you really
> think his is a valid point of view, that everyone else should jump up

> tell us what we should do?

I dunno. In my fields I get a *lot* of commentary and
suggestions-sometimes things I've tried long ago and discarded because
they simply don't work, or is talking about.

Which reminds me of a story about FDR....

During WWII, FDR had an important meeting with Stalin. Eleanor
Roosevelt often sat in on these meetings. Stalin Told FDR "It is of
vital importance that America increase aid to Russia, and decrease aid
to Great Britain. It is with us that the most important battles are
being fought."

FDR stroked his chin thoughtfully and said, "Josef, you're absolutely
right!"

An hour later, Winston Churchill also had a meeting with FDR. Churchill
noted, " It is imperative that aid to Britain be increased, even if you
have to reduce aid to Stalin. Our front is the most critical of the war".

FDR took a drag from his famous cigarette in its holder, and said, "Winston, you're absolutely right!"

After Churchill left, Eleanor came over to him in a huff. "Franklin, those two men came to you with exact opposite demands, and you just told them both "You're absolutely right." That's wrong!"

FDR looked at her, smiled, and said, "Eleanor, you're absolutely right!"

Point is I could get irritated and angry with them, but there isn't much point.

> I really do think that a caustic comment was appropriate.

You're absolutely right! 8^)

Just kidding Roy!!!!!

I was just a little surprised, because it seemed out of character. No big deal

Now, here you have a key. The youthful number in any group define its' likely-hood of survival... it will be "they" who free us from strangle-holds and limits now imposed...

It will be the vast numbers of youth who end up defining the real future... without youth--we are all DOOMED (Viagra won't even help!!! <grin>)

Me? I would like to think, "I am just a guy." In a generic sense, a "John Smith" of society...

Long time ago I was a boy scout leader, still teach an evening CS course at a Jr. college (but, have been at odds with admin., my department head, I think the kids like me (most important--and they are ok...), most women ditch other instructors/professors to take my course(s)--I like the idea of them in the field)... many "older" students in my class... this year it is Java (yuck)...

... work digital encryption/decryption methods/implementations here, just to keep out of the unemployment line...

...my first computer was a mainframe, my first desktop an apple--I recognized a "better idea" (IBM) when it came along... trust me, I am a "geeky type"...

I set up a network in my garage so I could keep up with youth and remember mine, but now I have little to offer them, they keep the net and it has inspired some into the field...

Everyone is aware of my fondness of radio, and I do make known what is available here--but placed besides IM and internet communications--radio is a pale color to the net...

I am best at surfing the net, email and newsgroups for "entertainment/hobby pursuits"... I tinker, now and then with antennas...

... sorry to bore you... I really am as interesting as a rock!

Warmest regards,
John

I don't think anybody filters because of this. If the presenter of such
debate has a reputation as in your first example...all bets are off.
That is for me to imply that mud-slinging, name-calling, goading or any
wild-eyed radical or raffish behaviour, in spite of the best intentions
of the poster, will cause his occasional good points to be overwhelmed
by the cacophony of kill-filters at work.

>me...

Tsk. Then your card doesn't seem to be plugged in to
the right slot. I have 20 years on you and began in
HF radio communications 52 years ago. What you have to
understand is that EVERYTHING can be made "obsolete"
in the marketplace...HF is NOT used nearly as much for
communications now as back a half century ago. So, you
are "suddenly realizing" your "place in the world" is
getting smaller? Pass me your TS card and I'll punch it.

>When the "Dick Tracy Wrist Radio" is finally designed and
>implemented--perhaps there will be a "death of homebrewers" (I myself
am NOT
>much of a 'watchbuilder')--but until then we can have fun!

I'm wearing one right now. Made by La Crosse. Cost all
of $30 with shipping. "Tunes in" every night to WWVB
and sets itself to the correct time from a kilomile away,
even adjusts for Daylight Savings time. <shrug>

I'm not sure what everyone is talking about in this thread but, like Roy and a few others, I've seen some innovative (and sometimes inventive) work in the many and various disciplines of "radio" and electronics in the past half century.

You want "modularity" a la a PC? WHY?!? Because it is "familiar?" Because it is "cheap?" Here's a clue: This newsgroup is NOT a "production design and marketing newsgroup." It isn't a political science discussion place to whine and moan over some middle-aged anguish angst attack.

MODULARITY has been going ON in electronics ALL OVER since the designers stopped trying to use transistors as if they were vacuum tubes. I have a nicely working Icom R-70. It is VERY modular, built NOTHING like what a PC is, NOR SHOULD IT BE. A cast frame and cover that has a rectangular box form...for convenience on a desk ...but everything inside is MODULAR, grouped to take different boards for different models, different functions. Those MODULES are mostly soldered together, those MODULES "sitting" in unlikely positions within that box. I have another receiver, a National NC-57, all tubes, all boat-anchor, purchased in 1948 with my own money (about $95) and it works, to be polite, like BADLY in comparison.

Icom has done the MODULAR thing, so has Yaesu, and Kenwood, and Collins Radio, and even Heathkit. All did it DIFFERENTLY than any IBM-clone PC. I think ALL the "radio" makers have done things differently AND done the MODULARLY...even those that had only ONE module.

On the other hand, I'm typing away at a "slow" PC which has a processor chugging away at 2.4 GIGAHertz with memory access rates up in the 100 MEGAHertz range. Now, from what I've learned and experienced, such frequencies ARE RADIO. With newer PCs the memory access rates go above 200 MHz...and the generated RFI is LESS than my first "powerful" PC with a 20 MHz clock. Why? Better IC transistor junctions taking LESS operating power. MUCH LESS. Less power in those state transitions, ergo less radiated stray RF. Three thousand cheers for that! I'm looking at an LCD flat screen monitor which is far better to watch than the old CRT "monitor" and has much less RFI than that CRT.

I passed 52 some time ago, had maybe 15 minutes of middle-age angst/worry/regret/etc., shrugged my shoulders and carried on. There's way TOO MUCH delight and wonder of all the new things coming out, the wonderful new (some marvelous improvements on the old) components, fantastic circuit and system simulation for

"breadboard" trials, all sorts of SOC (systems on a chip) by mail-order from dozens of vendors. It's a marvelous fairyland chock full of goodies to use in all kinds of hobby construction in new and different ways. Why sit around and contemplate radio navels and make noises of badness or arouse controversy to get your anonymous name "known" in a newsgroup?

A very long time ago I learned a truism: Electrons, fields, and waves don't give a @#$%!!! what humans think/feel/emote-about. They work by THEIR laws, NOT by some emotional advertising copy or glossy looking shelf items nor by the "reviews" in hobby publications nor by all the cussing at them by builders who don't know what they should be doing.

Having said that, I'm going to continue putting together an EPROM burner so that I can complete a MODULAR SW BC receiver that is single-conversion with a 21.4 MHz crystal-filtered IF and has a PLL for the LO. "Auto-bandswitching" just for those SW BC bands yet the LO tuning range is continuous. It's in a little BOX made of double-sided PCB stock, 4" x 8" x 8" in size. Not one microprocessor in it...done that way on purpose. Could have been done a decade ago with nearly the same parts.

There's PROGRESS all over the place. If one keeps one's eyes open. <shrug>

Microdyne (L-3Com) made telemetry receivers that plugged into EISA,
PCI and VME busses. They were very expensive due to the problems of
shielding the modules and having a wad of miniature coax cables and
connectors running between sections. The RCB-2000 (VME based) system
was $80,000. You got that kind of money laying around?

What happens when you have compatibility problems between third party
modules, or need support for a board and the company is out of
business? Who do you expect to put up the money to develop the first
units? Do you think the prototype will work so well that you can ship
it? How many man-years of development do you want to pay for? How many
do you expect to sell? What happens when they change the buss type or
speed, again? Have you ever done any PC or commercial RF design?

Yes, the young deserve a better future--one only has to hear the past to be reminded of that...

Cheaper is better? Yes and no. If it means a superior product and more affordable and provides the means of putting more radios into more hands--yes, quite an improvement I would say...

"Planned obsolescence", well, that is one way to look at it--the car replacing the horse and buggy is another....

Or, you mean we have the technology right now to build and market the processor we will be using in 10 years? 5 years? 3 years? I think not--this world is changing much faster than just a decade ago, before this year has ended--faster yet....

Somehow, the point is being missed, providing such a platform "empowers" many more minds to contribute... that is really what the IBM clone and standard case/power supply did--otherwise, there was/is the Mac... ten years ago I used a 486-100 Mhz, the Pentiums were still pretty new and I had not upgraded yet, today a 3+ Ghz machine--I think you give "them" far too much credit if you think that was "planned obsolescence", however, the faster machine was indeed planned...

If your argument is that I can open the case of my transceiver and start hacking away--well, I guess I could--but, much better if it were designed so that the changes were not permanent, could be revoked, or could be changed again, and back, and quickly...

But, I do keep getting a clearer and clearer answer to why there has been no progress...

How many here are younger than I? Younger than 40? Younger than 30? Younger than 20? How many here ask "Why not?" as opposed to "Why?" Etc...

You know, such an idea is NOT revolutionary, did you notice I really mocked "innovation" in the first reference?... it isn't innovation really, it is leaving the stone age after watching others drive by in cars, for years!

This article, over a year old even makes note of similar views...
http://www.arrl.org/news/stories/2004/05/17/1/?nc=1

What do the younger guys here think? Or, has he already spoken?

Regards,
John

I was a volunteer advisor for the Lake county Florida Vo-Tec
electronics program, till it was shut down. Right now I am trying to
find the money to finish repairs to my four car garage and convert it
into a 1200 sq ft electronics shop to teach basic electronics to the
kids who are still interested. Its not easy when you're 100% disabled
and living on a tiny pension, but I don't give up too easy.

I agree that it would be quite hard to make a good quality radio with
some common backplane structure. However, connecting various
functional modules with 50 ohm input and output impedance could be
used to make quite different radios with good specifications. For
instance Mini-Circuits also makes various diode ring mixers,
amplifiers and apparently also VCOs that are boxed and have BNC or SMA
connectors. With each functional module in a metallic enclosure,
controlling the spurious radiation between modules is much easier. I
don't know that anyone would make filter modules, which would be
required to build a complete radio. Also SSB-Electronics sold separate
amplifier, mixer, frequency multiplier and crystal oscillator modules
mainly intended for a 10 GHz transverter.

Unfortunately the cost of these modules is quite high, apparently due
to low production volumes and large amount of manual labour needed to
assemble them. If there would be a large demand for such modules, it
would make sense to design them to require less manual labour to
assemble them and hence get the price to more affordable levels.

While a backplane would not be suitable for running the RF signals, it
would be a good idea to have a common control interface standard. This
might be some sort of serial interface or perhaps a CANbus interface
as used on some AMSAT satellites.

Well not quite correct.

I have not used my receiver(DAR-WS2000) for a while since I can only point at the satellite from my garden and what with the English weather !!

It's tuned to AfriStar.

I tried yesterday and most of the stations I could pick up are now locked. Picked up a Worldspace station asking if I wanted to subscribe ?

Fuck-Off I only listen to RIFF ! I like jazz.

Get people interested and then charge.

I don't suppose there are any hack-codes ?

Anybody want to buy a barely used DAR-WS2000 ?

On an example like a simple homebrew 2 tube regen set it is typically recommended to use a metal front panel to "shield" the ckt from hand effects. However, you can still notice some effect by touching the ground/panel.

Would one see any advantage by using double-sided PCB with the two sides not electrically connected?

> Roy Lewallen, W7EL
==========

Would a relatively 'low cost ' plug in card system perhaps be possible by using standard PCI (computer) or similar card connections for the 'non RF' connections ,with standard 50 Ohms miniature connectors for all RF connections.
It would mean that all RF card modules would have a standard RF in- and output connector using 'miniature coax'.
It would of course mean that all the card modules involving RF would have a universal 50 Ohms in- and output impedance.
The latter is already promoted by looking at designs in the book 'Experimental Methods in RF Design'

The above referred type of PCI card connections (or any other agreed card standard)could then be standardised with specific 'edge connections' used for 'ground' , +5V , -5V , +12 to15 V ,-12 to 15 V , etc

The above would facilitate home brewing and make it possible to combine home brewed modules with specialised commercial modules. It also would enable testing modules with standardised (impedance wise) test equipment.
Ready made or blank (single or double sided) PCBs would have identical 'card fingers' also those supplied as part of a complete kit.

I feel that the amateur radio community would very much benefit of such a standardised card system.

Although the amateur radio market place is relatively small , with modules physically standardised , there would be an opportunity for a modest 'cottage industry' .

> [Hand capacitance detuning receiver]
> double-sided PCB with the two sides
> not electrically connected?

My gut feeling is that hand capacitance (maybe tens of pF) is small compared to the capacitance between the two layers of PCB (hundreds of pF) and that the shielding effect would be negligible.

Now, "guard ring" style shielding (as used in high-impedance PCB layout) might be worthwhile, but would be more difficult to implement.

Tim.

Thanks for the reply. Here's the logic that is making me ponder this.
The capacitance of the PCB would be in 'series' with the hand
capacitance resulting in a lower overall capacitance.

If I plug in numbers like 200pf for the board and 20pf for the hand I
see that the numerical improvement is minimal but I wonder if it can be
expected to work that way?

-Bill

2377. FS Teflon wire at Dayton

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-05-09 15:08:15 UTC
From: James Skalski <jskalski@yahoo.com>
Message-ID: <427F44DB.6030704@yahoo.com>
Source record: 19010
Cross-posted to: rec.radio.swap,rec.radio.amateur.homebrew

I will have some Teflon insulated, silver plated stranded 22AWG wire for sale. It is 5 fifty foot rolls (250 feet total)
At least five different colors. The wire is rated at 200C and 600V. Price at Dayton $7 per pack of 250 feet. I will be at Flea market space #320 I will be there at 8,10,12 and 2 pm on Friday and Saturday. (It is a flea market and I will be wandering about at the other times looking for stuff that I need) So I will try to be there at the "even hours" listed...

If you could use larger quantities you can reserve 1000' spools of 22 AWG teflon wire for $20 per spool. You must contact me in advance with your callsign. I will be limited by weight and space requirements.You can also stop by to "fine tune" the pickup. Maybe you can get it at Salem Mall parking lot to avoid carrying the spool/s.

Yes, but there's always an outside chance that it'll do some good.

If the chassis of the set is not referenced to the same ground that you are then touching the chassis will change the effective capacitance of the tank circuit. This effect will probably be greater if the antenna is capacitively coupled rather than inductively. The two things that I'd do before experimenting with the PC board would be _first_ to make sure that the chassis of the receiver was brought to a good ground in the station, and second to consider putting the entire receiver into a shielded box.

So we might all get on the same page, here is a list of "troll definitions."

1) a newsgroup post that is deliberately incorrect, intended to provoke readers; or a person who makes such a post

2) From the fishing term. As a noun, synonymous with flamebait. As a verb, to post controversial or provocative messages in a deliberate attempt to provoke flames.

3) to fish with a bait or lure trailed on a line behind a slowly moving boat.

4) From the fishing term. As a noun, synonymous with flamebait. As a verb, to post controversial or provocative messages in a deliberate attempt to provoke flames.

5) This is the Scandanavian term for elf. Sometimes they are described as being hairy and ugly, although they are able to change their shape into anything they please. They are said to have lots of treasure, and live in beautiful palaces.

6) SCA term for gatekeeper or door warden at a feast or other event. This name has no historical basis. "Porter" was atypical medieval name for this job.

7) a race of giants. They appear in various Northern mythologies. In Norse mythology Trolls are represented as a type of goblin.

I assume you are meaning definition 1) as your definition of me being a "troll."

Do you feel anyone opening a discussion is a troll? Is there always a "troll" at the center of every discussion? Is the only discussion without a "troll" one where no one has made a statement to open it--and therefore--it is really a "silent discussion?"

Is a "troll'less discussion" one where everyone agrees with you?

Your accusing me of being a "troll" is, in my opinion, really "character assassination" on your part--although you cloak this knife in velvet, the gleem of its' blade is still seen...

Regards,
John

Source record: 19016

Roy pointed out to me in email that the highpass versions have a positive phase shift, which is different behavior than a transmission line. However, they do have the characteristic that they reflect an open circuit as a short, and a short as an open, and an Ro load as Ro, which is the behavior you want for the PIN switch. The phase shift in that application should not be important. In general, both the pi and T versions, and for both highpass and lowpass configuration, reflect a load Z as (Ro^2)/Z, I believe, where Ro is the reactance of each component.

Cheers,
Tom

No, not all discussions are trolls.

Some of the things which tend to make me consider a posting to be a "troll" rather than a "discussion", are indications that the original poster isn't really interested in an honest discussion. Typical signs:

- Poster shows up with a big dose of attitude on his/her shoulder. Phrases like "You people are all laughable idiots" (fairly common among spammers posting in the anti-spam newsgroups), or "Obviously, anybody who has a brain will agree that xxxx is true" are red flags.

- Posters who respond to criticisms of their proposal by ignoring the technical validity of the criticisms, or by attacking the critic rather than the criticism (ad hominem responses), or by glossing over the criticisms without a serious response (hand-waving).

- Posters who seem to fail to "think through" the consequences, and costs, of their own proposals and ideas.

> Is the only discussion without a
>"troll" one where no one has made a statement to open it--and therefore--it
>is really a "silent discussion?"
>
>Is a "troll'less discussion" one where everyone agrees with you?

No. A troll-less discussion is where everyone involved engages in an intellectually honest debate about the merits, disadvantages, and costs of the suggested ideas(s). There are plenty of such troll-less discussions, on USENET and elsewhere, where the debaters disagree quite strongly!

>Your accusing me of being a "troll" is, in my opinion, really "character
>assassination" on your part--although you cloak this knife in velvet, the
>gleem of its' blade is still seen...

Well, here's a third-party opinion. It's free, take it for what it's worth to you.

From where I sit, it seems to me that your style of proposal and debate are somewhere in the middle. They are not blatantly "troll-ish" (in the sense of someone who is posting purely for the joy of stirring up a fracas), but neither do they seem to be a completely

serious attempt to discuss the actual merits of your ideas (as compared to the alternatives).

The somewhat troll-flavored signs I observe: well, there's the rather inflammatory and biased declaration you made in the subject of "No progress in decades." I call this trollish, because it *presumes* the validity of the very idea that you are proposing (i.e. that a modular, card-based radio architecture is the best one) and because it ignores all of the progress that radio systems have made in other areas of implementation. It seemed more inflammatory than communicative.

I also see your response to some of the criticisms posted (including my own) as somewhat trollish, because you seem to have responded to serious counters by either handwaving around them, or by condemning the poster's effort to respond to you (e.g. your comment that you "aren't looking for people who'll tell [you] why it won't work, you're looking for people who'll tell [you] why it will.")

One of the essentials in any scientist (and, I think, in any good researcher or proponent) is intellectual honesty, including the ability and willingness to figure out the weaknesses and limitations of any theory or proposal, as well as the strengths. I think you'd find your proposals received rather better, if you showed more clearly that you were willing to think them out to this degree in advance of posting them, and were open to receiving honest criticism.

No. A single side is adequate.

What causes the change to occur when you touch the panel is that oscillator current is flowing on the outside of the panel. The way to avoid this is to completely enclose the oscillator with a shield.

2389. Suggestions for VHF-AM Transmitter?

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-05-09 19:01:40 UTC
From: Netgeek <no_spam@comcast.net>
Message-ID: <xMGdnfGbgcE8LuLfRVn-hw@comcast.com>
Source record: 19021

Quite a few weeks ago I posted looking for info on VHF-AM receivers and received a number of pointers to additional resources and study material. Thanks to all who responded and, in particular, to Pete-KE9OA who has been a tremendous help!

Since then, several protos/learning platforms have been built and I'm pleased with the results overall - great learning experience (which continues).

Now I'm interested in the transmit side of the equation and have been poring over the 'net and other materials/articles trying to get a grip on this part. So far I have a block diagram (or "blockhead" diagram more accurately 8-) of a two stage Mosfet widget using some VHF parts from Mitsubishi. Specifically, I'm thinking:

20 mW LO input -> RD00HVS1 Mosfet -> .5W -> RD06HVF1 Mosfet = ~6W output. Modulation either transformerless (or transformer) using something like an audio amp (e.g. LM384) after suitable compression/limiting. Net result that I'm after is approximately 6W output using a 12-18VDC supply. So.....

If anyone here can point out some worthwhile texts, articles, or similar designs that might apply I'd be grateful.

BTW, before this sets off a string of cautionary tales and admonishments about newbie nitwits playing with transmitters (especially at Airband frequencies) - I can tell you this is a "bench only" project intended to feed a well-grounded 10W/50ohm dummy load ONLY... Are you kidding? I live in Arlington, VA - within walking distance of some of the world's biggest paranoids. I already worry about the splatter created by the blender when the wife and I mix up a batch of Margueritas! (we try not to simulate any "modulation" by hitting the "pulse" button 8-).....

Thanks for any help,
Bill

That's already been done in the RF industry for a half
century.

As one example, take the U.S.' AN/PRC-8, -9, -10 series
of manpack transceivers covering high-HF into low-VHF.
Still in the vacuum tube era, all of the IF modules
included the IF tuned circuits as well as the subminiature
tube. If the tube filament burned out, the entire module

was replaced. NO alignment tweaking was required. Design
was done back around 1950.

As for standards on control...start with the ATLAS (for
USAF test equipment) and continue on to the IEEE-488
interface. Those standards worked with "modular"
components capable of testing receiver sensitivity down
to noise level with KNOWN signal levels. By the way,
test equipment for RF has been standardized at 50 Ohms
since WW2 days.

Define "more affordable." :-)

"Filter modules" have and are built to order by dozens
(if not hundreds worldwide) of companies. The costs
ARE high because they are built TO specifications and
such have to be TESTED to meet those specifications.
Is there comparable KNOWN/calibrated test equipment
in the average homebrewer's hobby workshop that is
comparable...even at "low" frequencies of HF? Actually,
Kaylie's Mini-circuits DOES use calibrated, automatic
test equipment to check out each module, small
quantities to large quantities. Mini-Circuits doesn't
have the market demand to do production runs in the
10,000-lot quantities.

The mystique on L-C filters is largely that...mystique.
Without some good, calibrated test equipment, it is
very difficult to determine what a "filter module"
has for performance. Synthesis (design) of the values
for a particular filter type was arduous until folks
came out with computer-aided design. I have a working
freeware program for PCs on that...send a message in
private e-mail if you want one transmitted to you.

As to cost, just look at a cellular telephone handset. Those can cost around US$ 50 each, new. They work in a band roughly centered at 1.0 GHz. Microwaves. Complete microwave Rx-Tx with synthesized tuning. For half a hundred US dollars here. A mere 30 years ago that would be almost inconceivable. Three years ago the U.S. Census Bureau said that one in three Americans have a cell phone subscription. That's roughly 100 MILLION units either out there or waiting to be used. Market quantity and competition in that market are the key to bringing down costs. Radio hobbyists just cannot possibly get close to such market quantities.

>While a backplane would not be suitable for running the RF signals, it
>would be a good idea to have a common control interface standard. This
>might be some sort of serial interface or perhaps a CANbus interface
>as used on some AMSAT satellites.

Who says a "backplane would not be suitable?" :-) Those PC backplanes carry terribly broad spectra of RF...from (literally) DC on up to the low microwaves. No "perhaps" about it. Thing is, the layout can NOT be done as if it were wire-wrap; i.e., in random order of wire placement. With broadbanding anything, every single adjacent trace becomes a COUPLER and unwitting layouts can produce remarkable crosstalk effects. Designers have known that for decades and handle it...all kinds of Application Notes and info out in public access available for anyone...just too specialized for the "weekender" small-project assembler hobbyist.

The IEEE-488 is a mature standard for control and interface for computer-controlled, interconnected systems. Would be a bit TOO all-inclusive for a special-purpose new design. The "interface" does NOT have to be some kind of "new" thing used on the latest whatever out in space. It's just a control-and-response avenue carrying signals of a standardized kind...a few wires/traces perhaps...laid out properly if required to be broadbanded or broad in dynamic signal range. Not a big thing, but needs some THOUGHT before becoming hardware.

I don't think much of the discussion has looked very closely at what I think is envisioned here -- a mainframe which would accept various "cards" from numerous vendors. As I detailed in an earlier posting, it's tough enough (and costly) to make a robust interface when a single company has full control of the mainframe and plugins. But let's think a little about the problems of making a mainframe which could accommodate cards from various vendors -- cards which have different performance characteristics.

The first question is, who will define the interface? Who will dictate modifications as they become necessary?

Then let's consider a vendor who wants to make, say, an audio amplifier card. It has digital signal processing with a dozen different modes. Each mode has considerable adjustment range, for example the width of a bandpass filter. The interface would have to have pins dedicated to these functions, and the front panel would have to have switches and controls for them. How about an oscillator? One might be digitally tuned, another analog. There are bandspread and RIT to accommodate in addition. What do we do about T/R switching and timing if it's to be used in a transceiver? How about shielding specifications so it won't interfere with other cards?

The only possible way I can see something like this being even possible is for a virtual "front panel" being done in software and appearing on a PC screen; only in that way could each card be sure that the necessary controls would be present. Some sort of serial bus with expandable protocol would be used for all controls.

Then the question becomes, who will define, develop, and maintain the software? I can tell you from experience that it's no easy matter to keep any software working properly as new operating systems, protection software, and hardware appear. Add the necessary hardware interface to the equation and the job gets tougher yet. Oh, and what do you do when key components of the interface become obsolete and no longer available?

It's common for people who've never had to design something which will be reproducible by the thousands and operate without error, to say how easy something will be. As one of those people who spent a career designing just such equipment, I'd bet serious money that the cost of development and maintenance of the interface would never pay itself back in sales. Unless, of course, it's done by volunteers. My question is: Why don't folks like "John Smith" get off their duffs and do it?

hello all,

has anyone taken a heathkit HD-15 phonepatch and converted it as a computer interface for the digital modes? i have seen a couple of these but no one ever has the schematic or they are not wanting to take the time to explain.

any help and ideas would be appreciated.

... I forgot to mention, that while the minimal OS of the radio itself would be a minimal linux kernal--a USB, TCP, serial, parallel, etc hardware interface could be chosen so windows users would find it transparent--and they access the radio either through a GUI or commandline interface... when using the digital capabilities...

The most basic starter of this radio might be a regen receiver (or TRF) and a one watt xmitter board and analog of course... great for new "bootstrapping" hams...

Warmest regards,
John

Hmmm, you know, basically just two guys built the first apple desktop computer--you think it is that much more difficult? Well, maybe!

I think one can begin with at least a mental pic...

...all the voltages which are to be used run on a common bus, the digital lines are there to, without the "motherboard card", these are pretty much unused... the audio lines can be hear for digital cards (on the bus for the audio amp card)--very low level rf might have access though a proper connector, of some sort (maybe on a shelf now, maybe need to do new specs for one), there is a bnc/so-239, etc... which "floats" in a slot, capable of sliding along to gain access to all cards (why limit where the PA will be inserted?)...an analog bus with connectors available to each card lays on a line which is also available to any cards requiring it, and provides connection to a plug which is accessible if an analog panel is used--on this analog panel are standard components (which may be all there, or added one at a time, as needed)--meter, vol, squelch, rf gain, tuning (variactor card, or old variables if room) lcd readout, etc...

Certainly one would just begin with the case, power supply, and the bus(s) providing everything one can imagine a "card designer/builder" would require in the future--and put some flexibility in it, just in case you want to do a case revision/upgrade in the future, maybe you start out with too big a case right now--looking forward to future times when it would be desirable to have it smaller, etc..... rf out, rf in?, audio, etc lines--duplicate most everything in both digital and analog-- ... then "analog panel"/"digital panel" connectors... maybe expect the case to house no larger than a 100-500 watt PA... larger power through an external unit...

You point is well taken that my bench, time and abilities are limited--I am trying to finish putting three boys through college...

... even my overpaid colleges at work just wanna sip beer on the weekends and watch the game or dvds, or plan the next cruise--could be a sign of my generations age or decline... my access to real "innovators" is limited... so is this countries...

... but, as has been pointed out--this newsgroup is read in other countries... countries where innovation is not dying but, rather just blooming...

And, placed beside the first apple desktop (built by, basically, two boys in a college lab and a garage)--I think most would say "IT IS DO-ABLE!"

Warmest regards,
John

Well, most of this requires VERY little innovation and only DUPLICATION...

Many manufacturers make motherboards, hd's, cd's, video cards, audio cards, tv cards, radio cards, network cards, port expansion cards, home security cards, security cams, credit card readers, security readers (finger print, eye retina, etc) etc, etc...

... That many manufactures share one case with great ease--is made obvious by the computer on your desktop--indeed--on excellent motherboards, they are NOT picky about even the processor!!! Intel, Cyrix, AMD, IBM, VIA, etc (even providing sockets with different pin configurations for different processors!)... (Some no longer available--they come and they go)

Don't go name brand junk: HP, Dell, Toshiba, Sony, etc--but go generic IBM case and the world of computer manufacturers is available to you... and look at the laptop--you know why EVERYONE in the world doesn't have one? BECAUSE THERE IS NO GENERIC CASE!!!! You are stuck with proprietary junk!!!

Both in rec.radio.amateur.antenna and here there are far more focused on why something can't be done, than why it can--I think if one ignores this--it can be done!... this is interesting... and is why I began a thread on progress.... especially since so many thought there was no reason to even mention it...

One more thing, just make a generic case for a laptop platform, make the platform available to support other manufacturers components--guess what...

Warmest regards,
John

news:117vrtch8oul0da@corp.supernews.com...
|I don't think much of the discussion has looked very closely at what I
| think is envisioned here -- a mainframe which would accept various
| "cards" from numerous vendors. As I detailed in an earlier posting, it's
| tough enough (and costly) to make a robust interface when a single
| company has full control of the mainframe and plugins. But let's think a
| little about the problems of making a mainframe which could accommodate
| cards from various vendors -- cards which have different performance
| characteristics.
|
| The first question is, who will define the interface? Who will dictate
| modifications as they become necessary?
|

| Then let's consider a vendor who wants to make, say, an audio amplifier
| card. It has digital signal processing with a dozen different modes.
| Each mode has considerable adjustment range, for example the width of a
| bandpass filter. The interface would have to have pins dedicated to
| these functions, and the front panel would have to have switches and
| controls for them. How about an oscillator? One might be digitally
| tuned, another analog. There are bandspread and RIT to accommodate in
| addition. What do we do about T/R switching and timing if it's to be
| used in a transceiver? How about shielding specifications so it won't
| interfere with other cards?
|
| The only possible way I can see something like this being even possible
| is for a virtual "front panel" being done in software and appearing on a
| PC screen; only in that way could each card be sure that the necessary
| controls would be present. Some sort of serial bus with expandable
| protocol would be used for all controls.
|
| Then the question becomes, who will define, develop, and maintain the
| software? I can tell you from experience that it's no easy matter to
| keep any software working properly as new operating systems, protection
| software, and hardware appear. Add the necessary hardware interface to
| the equation and the job gets tougher yet. Oh, and what do you do when
| key components of the interface become obsolete and no longer available?
|
| It's common for people who've never had to design something which will
| be reproducible by the thousands and operate without error, to say how
| easy something will be. As one of those people who spent a career
| designing just such equipment, I'd bet serious money that the cost of
| development and maintenance of the interface would never pay itself back
| in sales. Unless, of course, it's done by volunteers. My question is:
| Why don't folks like "John Smith" get off their duffs and do it?
|

BAMA (http://bama.sbc.edu/) has the heathkit HD-15 manual online here:

ftp://bama.sbc.edu/downloads/heath/hd15/

Don't know 'bout using it for digital modes. Got one myself... will have to
investigate.

Thanks, Steve

The PCI signals must run on transmission lines, since the receiver is not activated by the for forward wave, which is reflected by the mismatched end of transmission line and the receiver is only activated by the combination of the forward and reflected wave. So indeed, the layout is critical to get the signal through, even if no crosstalk problems would exist.

In a PC, the signals are all around a few volts, thus the crosstalk problems are not so bad. In a radio receivers, the signal levels vary from less than a microvolt to several volts, so the crosstalk issues are much more demanding. Microstrip transmission lines would hardly be enough, at least striplanes with grounded traces between the signal conductors in the middle layer would be required, so the minimum would be a 3 layer PCB.

The IEEE-488 requires a lot of signals and a complex handshaking, so in practice, you would need an interface chip anyway.

The CANbus has been used in the automobile industry for more than a decade. The CANbus has a nondestructive collision system, so this makes it possible to have a true peer-to-peer communication system, without complex protocols (such as token passing).

The AMSAT thing I was referring to is a standard PCB, with a size about a D connector, with an interface chip on it and it has a few digital signals. It is included in every module on the bigger AMSAT birds. This bus structure greatly simplifies the wiring between modules.

There are large, well established operating system created and
maintained by volunteers. The problem with some special hardware is
often that the hardware interface specification is not publicly
available (as with some 3D graphics cards).

Writing a device driver for some radio modules would not be that hard,
provided that the module control is designed in a somewhat sensible
way. As long as the hardware interface specs are available for these
modules, the software is not going to be the show stopper.

These relays will usually hold in fine on 12 VDC they may even work OK. If
they will not work there is a circuit that charges a capacitor to 12vdc and
when the relay is energized the cap is momentarily in series with the 12
volt supply. This will pull the relay in then the 12 volts should be enough
to hold it. Google on "operating 24 volt relays on 12 volts" Circuit is very
simple if you can find it.One advantge of using this circuit is that the
relay coils are not stressed as much. A coil that runs hot at 24 may be
cool to the touch on 12.

But...there CAN be COUPLING there and that is, very
definitely, part of the layout. When mixed with
analog signals - as would be the case in a "radio" -
the layout can be critical.

>In a PC, the signals are all around a few volts, thus the crosstalk

Look again at the 3.3 V logic thresholds. :-)

>In a radio receivers, the signal levels vary
>from less than a microvolt to several volts, so the crosstalk issues

I will disagree on radio receivers on such wide dynamic
ranges. "Several volts" INTO a receiver front end?
No. Such levels aren't encountered in practical
locations and would, definitely, cause enough IM
that would create much distortion and spur products.

In radio transmitters, YES, but those stages can be
individually shielded and thus isolated...do NOT

need to be close to the control lines...or even need
control lines (in the case of an amplifier block).

> Microstrip transmission lines would hardly be
>enough, at least striplanes with grounded traces between the signal
>conductors in the middle layer would be required, so the minimum would

>be a 3 layer PCB.

Not the case in practical RF structures done in
the last three decades. [been there, done that,
got lots of T-shirts] It is BETTER to have good
stripline and microstrip as opposed to "ordinary"
PC layout, but that isn't an absolute necessity.

>The IEEE-488 requires a lot of signals and a complex handshaking, so
>in practice, you would need an interface chip anyway.

That was cited solely as an example of something
that IS mature and used daily in radio-electronics
testing.

>The CANbus has been used in the automobile industry for more than a
>decade. The CANbus has a nondestructive collision system, so this
>makes it possible to have a true peer-to-peer communication system,
>without complex protocols (such as token passing).

IF and only if this SDR of the future NEEDS micro-
computer control...or even modular microcontroller
sub-systems.

Trying to use an EXISTING computer interface system
isn't always good because that system has worked for
a decade-plus. While automotive computer interface
system speeds are increasing with increasing control
demands, radios aren't quite vehicles. The control
needs aren't quite the same.

>The AMSAT thing I was referring to is a standard PCB, with a size
>about a D connector, with an interface chip on it and it has a few
>digital signals. It is included in every module on the bigger AMSAT
>birds. This bus structure greatly simplifies the wiring between
>modules.

I've had hands-in on earlier unmanned spacecraft but
understand the principles...which are similar to the
interface chips for things like USB adapters to work
with Serial or Parallel port peripherals with PCs.
One SOC (System On a Chip) that is essentially a
dedicated mircocontroler is all that is needed.
[FTDI makes those chips, Mouser sells them]

What you describe is more like an outgrowth of the
existing microcontroller adaptation to amateur

radio (and, more, to commercial radio) equipments. The front panel controls are coupled (mostly) via DC lines to the actual signal controls on PC boards to reduce the mechanical complexity...which allows greater freedom of layout and compactness. [positive attributes for spacecraft as well]

My "ancient" Icom R-70 receiver has a central microprocessor doing a great number of control tasks...and does have some external control capability through a rear connector. At about two decades old, that's just one example of what already existed - in radios - some time ago and still does. Modern amateur transceivers usually have two microcontrollers. Some of those allow external control and a few are entirely controlled externally. The basics have already been laid down for the SDR system on what CAN work.

What is lacking is STANDARDIZATION. That can't be worked out in newsgroups, but requires much more organization...and willingness to compromise (almost impossible in newsgroups, heh heh). See any of the industrial standards (EIA, AES, etc. in the USA) which are the first steps towards making ANYTHING "plug and play." Example: The Cannon "D" connector was on the market in the early 1950s. A combination of factors made it a practical connector line used in many electronic things. Eventually, it became so common in the USA that it was Standardized in shape, materials, dimensions, etc., despite the original company changing in corporate evolution. Wide use made it "standard." The 25-pin and 9-pin D connectors are on practically every PC today...as they were in the beginning of the PC in 1981.

Standardization isn't anywhere close to reality for SDR now. Nobody can seem to agree on WHAT range of control is needed, let alone details of the controlling interface signals. :-) That might work itself out later.

You might want to check this.

I have dealt with circuits which "should have" worked, but enough
components pulled down the voltage to where relays would not stay
energized, and would rapidly cycle as they struggled to stay
energized.

Yes, i've seen this "pump-up" circuit but i would prefer a real 24 vdc to
make sure the rele is correctly energized.
My 26 vdc - 4 ways Dow-Key coax rele works also with 12 vdc, but the problem
is : "is it affordable at this coil voltage???"
A stronger 24 vdc would be better...

The really funny thing about Dilbert is that people who work in that
type of environment see only that the character names are wrong for
their office.

Reminds me of a Will Rogers quote, "I don't make jokes. I just watch
the government and report the facts."

Scott Adams worked in a high-tech office, and reports the facts.

In case you missed it, I was saying that I don't let these things get
me down. I find something to keep me busy. I could be like a lot of
people I've met recently who throw up their hands and give up on
everything, but I'm not like that.

The diabilty stops me from climbing ladders or carrying anything
heavy so I bought a large cart to move things around the shop and house.

The small pension makes me consider what I want to spend money on
rather than just write a check while knowing that I had a wad of money
in the bank to cover it, so it didn't matter.

Life goes on, if you let it. :-)

Michael,

If you don't mind my asking, what sort of professional electron wrangling did you do prior to becoming disabled?

Good luck on converting your garage... I think there's a good chance you can get a decent amount of equipment and supplies donated once it's clear (to the outside world) that you're serious about what you're doing.

----Joel

You can't see the forest for the trees. There isn't a big enough
market for what you want to EVER bring the price down to a reasonable
level. You can't do anything without some initial specifications. You
have to do research on available parts, cost to tool up the metalwork,
and liability for your design. You mention a "PA" implying a transmitter
module. You talk about "manufactures of the modules" This brings the
FCC, UL, and other testing costs and problems. You have no idea what you
are talking about, unless you have worked to design a modular system.
It can easily triple the cost of the design. Then there is software
compatibility. You have to set strict standards for each module, or one
"X" module won't work with someone else's "Y" module. How about the
GUI? who is going to write a new one for every combination of modules?
Or do you plan on having a couple dozen separate programs on screen at a
time for each function?

have you ever designed a complete radio system?

> I suspect, in the future problems will arise and be delt with--just recently

> "fixes" will be forced on those of the future...

I'm all too familiar with finding replacements for obsolete parts.
Both in manufacturing and repair. There is a mature product on the
production line. Purchasing comes running to the production manager to
tell them that the last manufacturer of a line of components has just
dropped the whole line, and we missed the "Lifetime buy" option by a
couple days. Do you drop the product, or do you redesign it? DO you
spend days or weeks tracking down surplus parts through a broker that
may or may not be good, and risk bad PR when they have a high failure
rate in the field? Been there, done that. The tee shirt was NLA.

I don't think the "apple boys" had ever designed a complete computer before they did--indeed, don't remember anyone else (or team of engineers, techs, scientists, etc...) doing a desktop before then...

You mean, China, Russia, India, USA, Canada, So. American, Mexico, etc--and every gov't, business, private individual, ham and cb'er... is not a big enough market... these things would be manufactured in China yanno!!!

Kinda like Mac's and IBM's, yanno.

Lets face it, it is most difficult to buy American computer boards, memory, etc--these radios would be the same... the computers are already made there, we would just be giving them one more task...

Warmest regards,
John

Look at a multitransmitter contest site with one transmitter on each band, the voltage induced to the receiving antennas for other bands can be quite large. Of course, in a competent receiver design only the frequency band of interest is filtered out before processing. However, if the antenna is connected directly to the backplane and the modules do their own filtering, the large composite signal on the backplane will radiate all around the system.

In non-contest sites large wire or log-periodic antennas can collect a quite large signal voltage (in the order of 0 dBm, 220 mV or more).

Also if the final IF is within or below the receiver tuning range and a diode ring mixer is used as the SSB demodulator with +7 or +17 dBm, you must keep this BFO signal and harmonics from entering the front end.

Even the SDR is going to need some switchable front end band pass filters in order to survive in the hostile RF environment these days with a lot of strong signals even in ordinary sites.

In transceivers, there would be several points that would need switching.

I used the CANbus as an example, since the cable can be tens or hundreds of meters long depending on speed and thus, it could be used to control some internal points in a transceiver as well as wire all devices in the ham shack as well as in the tower. For instance, the same controller could control the antenna rotator, command the antenna preamplifier to bypass mode, turn the transvertter into transmit mode, select the VFO frequency for transmit (in split operation) and finally turn the transmitter on.

<examples of previous control systems deleted>

> The basics have already been laid
> down for the SDR system on what CAN work.
>
> What is lacking is STANDARDIZATION.

This is definitely a big problem.

> That can't be worked out in newsgroups,

A newsgroup is a good place for open ended discussions between people with experience in quite different fields. This can generate quite different ideas (some useful, most less usable) than a "business as usual" attitude. It is a good idea to have a lot of new ideas to chose from than having no new ideas at all.

> but requires much more organization...

Writing a formal specification may require some formal organisation, but on the other hand quite a few successful RFCs in the IT sector are written by a single person or a small group.

> and willingness to compromise

That is the problem in formal committees, in which most delegates from various vendors have large commercial interests in the subject and in order to be able to produce even some kind of standard, all features from various vendors are included. This makes the final standard hard to implement properly or each manufacturer is implementing only a subset of the complex standard and thus, there is no real guarantee that two devices would actually communicate, even if both claim compatibility with xxxx standard (remember the RS-232 "standard" :-).

Have you ever looked at the schematic for the Apple II? It was bases
on the MOS technology 6502 processor and support chips. Its probably
the simplest "Computer" ever sold and most of the design was in the IC
data books, just like the original IBM PC was quite close to a sample
design published by Intel. The only real difference was that the design
was broken up into modules. Neither of the original designs were
anything to brag about. Monochrome displays, Apple's half assed
"custom" floppy disk interface that threw away most of the capacity to
keep it cheap. The PC was shipped with a cassette interface and no
floppy drive. It had BASIC in ROM, and was fairly useless until floppy
and hard drives were available to do any real work.

If you think this is an easy project its time to put up, or shut up.
Design your simple, "It'll sell billions" project and prove everyone
wrong, or just shut up.

I worked for L-3com/Microdyne at their Ocala plant as a production and engineering tech. I also worked with purchasing to find and qualify replacement sources for components, and the nasty job of removing long time vendors from our approved list. I worked in every area of the product line, built test fixtures, wrote test procedures and fought the apathy of a couple older engineers to fix old design problems. I knew more about our oldest products than anyone in engineering, so when a problem cropped up they came running to my bench to ask questions rather than take the time to research the old records. The last product I worked on was their RCB-2000, a dual DSP based telemetry receiver, to take it from the engineering prototypes to the production floor. I was laid off when my health no longer let me work overtime, even though I did more in an eight hour shift than any two other people on the line. Suddenly, I was deemed "Not a team player" because I could barely walk out the door after my shift. I was troubleshooting and testing the signal processing boards under a stereo microscope and I did most of my own rework rather than wait for it to go through the rework department. I hand soldered 288 pin SMD chips under the microscope. After the cleaning room was done, QC couldn't find my work on the PC boards. This radio was introduced to the market at about $80,000. One of the VME based boards in it cost about $8,000 to stuff, reflow and test. I miss the work, but I doubt that I'll be able to do that kind of work again, and the high tech companies have pretty well left this part of the country.

So, although your original argument was how difficult a bus and keeping analog seperate from digital which would share various signals--would be, then, when the argument was made that someone just picked up a bunch of on-the-shelf items and went ahead and done it... you flip-flop--to where now it was so obivious someone should have done such a simple thing LONG before them...

Yanno, you are pretty obivous here--you are like what has been "the standard method of operation." A long list of why it can't be done--but if someone can--its' easy!!!

Or, first it is impossible, then, once someone has done it--it is nothing...

Now, that is comming close to a "Troll!" And, that would be proven if once this is pointed out to you--you use that for a reason to spur more conflict...

Arguments and debates for the purpose of looking over what is available--of reaching a logical and organized ideas--are good--argument for conflict is not...

While some may take pride in finding all the reasons why something is difficult--or may end up to be "un-do-able" right at the immediate time... It is the guys who ignore all this and go ahead and do it which are remembered...

For every thing we have in this world today--there stands inventors, engineers, technicans, etc.. who could have easily decided it was either too hard or impossible and given up--thank gawd they were of a different breed...

Warmest regards,
John

It gives me rather considerable pleasure to report that Scott Adams also
appears to monitor, or participate pseudonomously in, some of the other
newsgroups and mailing lists I frequent. Incidents from more than one of
those groups/lists have appeared in Dilbert essentially unchanged within a
few days of being posted to the group/list.

Sometimes I think Scott works for WeBuildHighways, where I'm employed.

Which Apple computer do you mean? The Apple II? Steve & Steve built the Apple I before then (you can do see one down at the Computer History Museum in the bay area if you'd like) and I'd bet a nickel they had built other folks' designs prior to that (e.g., the old Rockwell KIM, perhaps some of the popular S-100 machines available at the time, etc.). It was "revolutionary" in a sense, but much more evolutionary from a dry, engineering perspective... but then again, almost everything is if you look closely enough!

If you still had some supervisors "on your side" who were willing to go to bat for you, you might have had very good prospects with a lawsuit based on the ADA? I'm sorry to hear your company ended up being run by folks who couldn't see the forest for the trees (or even the broad side of a barn for their sitting in the outhouse); it's an unfortunate trend in many companies (especially as they become larger), and I tend to agree with people who suggest it's often due to technical companies being run by business school majors (without any engineering experience whatsoever).

I wasn't legally declared disabled until January of this year, so I couldn't sue under the ADA. It doesn't matter now, because the company doesn't exist. It was adsorbed wholly by L-3Com. Several hundred people lot their jobs, they dropped all but the RCB from the product line and took less than a dozen people to their new plant up north.

I've also worked as a broadcast engineer, CATV engineering, and owned an industrial electronics company that did commercial sound, CCTV, MATV, and oddball systems used by local schools and factories. I built Ch 58 TV in Destin Florida from scratch, starting with a 1952 built TTU-25B UHF transmitter. I'm in my 50s, and I never planned to retire, but its being forced on me in several ways.

Still, I find ways to keep busy. I have a couple hundred databooks in my library. I repair oddball equipment that strike my fancy. Two current projects are a TS-382 audio generator and a National NC-183R rack mount receiver. You can check out my personal web site from time to time to see what I'm working on, and maybe find a manual or oddball part you need. The link is on the "Organization" line of the message headers. I am designing a receiver from scratch, but its slow going because I have to budget carefully for the parts I don't have in stock. The VA service office told me I'm allowed to make a little money from a hobby, but they haven't been able to give me a dollar amount, so I'm holding off trying to make a little extra money till I get their answer in written form.

Well, I am not even ready to argue that point...

You missed the point... what I propose is simpler... it is a radio--not a computer... and still can be done by those who ignore the nay sayers, no matter how loudly these nay sayers attempt to shout down progress...

I feel like a pimp in an old age home with hookers, no takers and everyone there wonders why I am there proposing the ideas I am... <grin>

Warmest regards,
John

You need to think with the other head, troll.

You have your head up your sorry ass, and I'm through wasting time with your nonsense. Its obvious that you don't know a dam thing about design when you compare the Apple II to a real design project. You need to get an education in design and stop trying to blow smoke up everyone's ass.

Have you ever heard the saying to the effect that the beginner sees only one option, which the experienced designer sees many? It really is something of a curse. :-)

By all means do keep pursuing your interests, but by the same token you might want to start learning more about RF design and understand where some of the other posters are coming from. Addressing your original idea, there ARE "modular" radios out there -- I know I've seen some guy's web site where he takes this approach -- but the idea that a modular radio can somehow offer the same performance as a more integrated one is about the same as claiming that you can build a CPU with the same performance and price of a 3GHz Pentium by using discrete modules for the ALU, memory controller, cache controller, instruction decoder, etc. -- it just isn't going to happen. On the other hand, you certainly COULD build some "many MHz" sort of microcontroller with this approach, and the sames of microcontrollers today swamps that of Pentiums anyway. Hence, I think there would be a market for your modular radio design -- especially within the amateur radio community -- but I doubt you'll be getting calls from Nokia any time soon.

Software defined radios accomplish a significant amount of the "reconfigurability" that I think you're looking for, and with ever-increasing ADC/DAC speeds and DSP horsepower, it probably won't be too long before most radios digitize directly at RF or IF and the rest is software (oftentimes highly non-trivial software, however). Even so, you'll always need someone who understands traditional RF engineering to get the signal from the antenna to the DAC while preserving the best SNR possible.

Say, does anyone have a copy of Joe Dixon's books, "Spread Specturm Systems" from 1976 and "Spread Spectrum Systems with Commercial Applications" from 1994? I'm curious how the content compares between the two.

I'd also be curious to hear the impressions of anyone who might have chosen to shell out the $190 (ouch!) for his "Radio Receiver Design" book?

Thanks,
---Joel Kolstad

I've got the former, but not the latter, and so can't compare them. If the later book is anything like as good as the earlier one, only with additional matter, I'll have to put it on my must-buy list. And now I need to investigate the "Radio Receiver Design" book. My bookseller thanks you, but my wallet doesn't.

Source record: 18971

Nearly ten years ago I had a project to design an ISDN terminal
adapter/router for "home" use. Once the design was completed I
(and several beta testers) had to install ISDN to our homes in order
to evaluate the product. We all lived in SoCal - with PacBell as the
provider.

We spent *months* going around and around with the PacBell
installers, CO technicians and the general bureacracy and so-called
"tech support" folks.

Eventually we gave up and decided to abandon the product and the
project - 'cause we realized that if *we* couldn't get things going with
PacBell there was NO chance for any potential end-user/customer.
The product worked great - we just couldn't get past the install phase
when working with PacBell!!!

A few weeks later I read a bio on Scott Adams and learned that he had
been employed by.....PacBell - in the ISDN engineering group!!!!!
Suddenly it all became clear - and I never laughed so hard...8-).....

I think that was Edison? Einstein said something like, "Creativity is more important than knowledge," which unfortunately a lot of people seem to want to interpret as "Hence, knowledge is unimportant," which is not at all what he meant.

> In the end, such a radio is not only desirable, it is exactly what is
> needed... no argument will change that...

Well John, there's nothing stopping you from desgining and building the thing. Even in the post-Internet boom era here, though, you'll probably have a much easier time finding venture capital from a bunch of businessmen than from a bunch of engineers.

I do think it's true that, in various areas, amateur radio now plays technological "catch up" to commercial technologies. IMO, this is a reflection of the fact that (unlike 40 years ago) designing a "modern radio" (such as a cell phone) costs literally tens to hundreds of millions of dollars and hundreds of man years. There's just no way companies like Icom, Yaesu, etc. can invest that sort of effort when you look at the sales volumes of their radios (and the fact that -- unlike cell phones -- amateur radio usage doesn't provide them with any revenue!). A lot of the most interesting advancements in amateur radio in the past couple of decades have come from the likes of Doug DeMaw, Bob Larkin, Rick Campbell, Roy Lewallen, Wes Hayward, etc. -- all of whom, insofar as I'm aware, spent some of their professional lives performing RF design for well-funded companies. I don't think that's a coincidence.

Joel:

Well, great men have come and gone, what are some younger names which will be taking on these challenges of the future? A history lesson does not serve as innovation or chat about new ideas which are needed...

I don't expect people in their 50's on up to be the innovators, it is the younger crowd who has been educated in universities, with access to the newest state of the art labs available which will be taking on these projects--that is a given, I never though different... if you didn't have access to a computer by jr. college, you are probably not in this group of new engineers...

The men in their 20s to 30s are the ones with the access to industry and design labs where these ideas can be taken to... the ones on the cutting edge--the ones able to introduce new ideas and get them looked at... the ones to build one and take it around to demonstrate...

I was just hoping there were some here, maybe not...

Warmest regards,
John

Nope the entire world wide population of hams is NOT enough. The US has just under 700,000. Japan has somewhere around 1 million (there numbers are hard to determine due to their licensing system). The remainder of the world combined has right around the same total of the US. This gives a worldwide ham population of under 2.5 million. So starting from that rough estimate, let's look at some figures. Very, very few people buy a new HF rig annually. Just using the people I know, it's more like every 5 to 10 years. So let's use an average of 7.5 years. That means a total of 333,000 new radios (rounding off the answer) sold in any given year. Now split that between 3 makers, yielding 111,000 units per maker. That's pretty low volume to undertake radical development. We're probably lucky that we get any new features.

Dee:

That certainly brings things to perspecive--doesn't it?, there are roughly 33 million (and uncounted illegals) here in calif alone... (I think canada is much less than Calif's population--so is australia)

The whole world of hams is only a small minority here in calif (more illegal aliens here!!!!)

But, I see your point, there is much more of a market in most any other area of communications, marine communications alone would be a larger market share... police/ambulance/fire radios probably are a larger share!!! Aircraft radios?

But, it would be better to market to gov't, industry, military, public service, etc... your point is well taken...

Warmest regards,
John

I think that's wildly optimistic. First, many, many licensed amateurs aren't active and don't own a rig at all. Another very large fraction buy only VHF/UHF gear. And, I don't know whether your figure of 700k hams with U.S. licenses includes the large number who are residents of other countries and also have licenses in those countries. Many of the foreign hams I hear from give a U.S. callsign along with their native one.

I think the only reason we get the radios we do is that the manufacturers can combine the design with equipment for other markets, such as public safety for HTs. I've read that the lack of 220 MHz HTs is because of the absence of a nearby public service band, so the manufacturers can't use the same design for both services. I find that believable. I don't know how important additional markets are to HF equipment development, or what they would be these days. My guess is that the manufacturers don't make an awful lot on their HF equipment lines.

In any case, the total market, particularly for HF gear, is surely much less than this estimate.

Hi John,

> Well, great men have come and gone, what are some younger names which will
> be taking on these challenges of the future?

I think Rick Campbell has gotta be 30-something or 40-something? I know one of his former professors, and that professor has only been a teacher for something like a decade now...

To some degree, younger folks are out there working at their day jobs. Not that I'll know for another few decades, but I expect that retirement gives one a lot of time to 'catch up' on their favorite ham persuits. Bob Larkin designed the DSP-10 software defined radio back in 1999 and -- while I'm making a lot of guesses here -- I believe that was not too long after Celwave (now defunct) bought his small company where he was designing and producing cell phone base station equipment and thereby allowed him a little more free time to design and publish for the amateur community.

> I don't expect people in their 50's on up to be the innovators, it is the
> younger crowd who has been educated in universities, with access to the
> newest state of the art labs available which will be taking on these
> projects--that is a given, I never though different...

Colleges today are a very different place than they were, say, 30 or more years ago. At least here in the US, it's pretty much "expected" that everyone at least attempts to receive a higher education, and this has caused a large change in college curriculum. To put it bluntly, it's become dumbed down and a shockingly large percentage of the students there really don't _want_ a highly challenging, rigorous five years -- they want a decent income in a reasonably secure industry (computers and electronics). Industry goes along with this because, realistically, what they need are predominently technician level employees and not true innovators or researchers.

Of course, for people truly interested in learning and innovating, there are probably more opportunities now than ever before (think of what Einstein could have done if he had been born in 1980...). What I'm arguing here is that it shouldn't be surprising that an increase in the number of college students and the availability of high quality test equipment doesn't translate into some phenomenally large spike in the innovation seen in amateur radio.

There is plenty of innovation going on in amateur radio right now. Winlink 2000 is a good example: many of the people who support it are the younger set, and many of the people who oppose it are the 'geriatric' crowd! Some of the true technical problems with WL2K -- such as the lack of busy detectors, best performance being obtained only with the proprietary PACTOR 3 modems, etc. -- have spurred additional innovation with results such as SCAMP. I actually

find it quite surprising that the most "digital radio" innovation seems to occur on the HF bands rather than VHF or above, but I expect this will change in the not so distant future. (I've mentioned before that personally I'm eyeing the 220MHz band -- very much neglected for many years now -- as prime territory for digital experimentation...)

You can't really be creative unless you understand the situation. On the
other hand, people can spout things but be unable to do anything with
it because they aren't extracting from the situation.

Creativity is an extrapolation. A good example is Charles Kitchin's
work with regen and superregen receivers. He went back, looked at early
material, understood it, and then implemented solid state versions.

Roy,

You make a lot of good points. I would like to see the return of 220MHz HTs! I am heartened to see that the stereotype of hams as tightwads has softened to some degree... perhaps it is all the boomers retiring and finding that buying a new rig every year or two really doesn't put too much of a dent in their annual vacation plans.

How many of those 2.5 million hams possess a copy of EZNEC, I wonder? :-)

Right... and this design approach might or might not be attractive to
them, given their specific needs.

You wrote earlier today of the new generation of youngsters, with
access to better equipment, at today's colleges. That might be a good
next place for you to consider floating this idea... you might find an
EE professor who would consider it to be an attractive design project
for a graduate-level (or high-undergrad) class in RF and electronic
design.

While you're there, you might also want to see if you could persuade
somebody in the business school tackle the other aspects of such a
venture... a market analysis, and a business-case justification.

For any such design to fly, it's going to have to make both technical
sense, and economic sense... as defined by the people you expect to
have buy/use it.

A miniscule fraction.

I get many requests to contribute EZNEC for a door prize and gladly did so, quite a few times. Not a single one of the stamped, self-addressed post cards enclosed with the programs was ever returned, which I've interpreted to mean that the recipients most likely never used the program. I belive that the vast majority of amateurs not only don't have EZNEC, but wouldn't have any use for it if given one. I no longer contribute EZNEC, since there's no point in giving as a prize something there's high probability that the recipient doesn't want. On the positive side, there are enough EZNEC users to have allowed me to stay out of the cube farm for ten years now. And they're a great bunch of folks.

Hmm... I suppose that, instead of the way it's usually done where every one is eligible for every prize, hamfests could perform raffles where people have checked off what prize they really want (give them so many "raffle points" that they can spend on various "priced" prizes they win if their ticket is drawn).

You could ask at FDIM how many of the people there have actually used EZNEC or a similar program. Besides L. B. Cebik, of course... :-)

Roy:

I have pointed out your EZNEC to the Ghz "Wireless WAN/LAN
Raiders"--"Wireless Cam Raiders"-- here...

Trust me, there are young minds attempting to design new antennas for
routers and tapping into wireless cams here....

I have seen some thought provoking ideas they are building... now the big
thing is "passive repeaters".... antennas to bend signals around houses
and down blocks... around sound walls, etc. But some are of even active
design... they sqeeze miles out of wireless router signal!!!!

These young guys can put some strange designs to work out of threaded rods,
washers, coffee cans, sheet metal, stovepipe, old 18"--6 foot aluminum
dishes, coathangers and bbq grills, short bits of copper wire soldered along
yardlong+ copper tubing, etc... EZNEC is there!!!

Farthest guy stays tapped in to the garage net here from his home 2+ miles
away... on a router/switch meant for home use!!!

My first antenna was a 120 ft long wire for sw--theirs is usually of a 2100
Mhz design!!!

Only thing I caution them of is high rf levels at these freqs--they have
little fear of microwaves until the dangers are made clear... they
constantly search ebay for microwave mosfets... when they mention ideas of a
PA out of a microwave oven--one does do some worry...

I built a crystal radio as my first project, didn't everyone back then? I
stand in awe....

Warmest regards,
John

Any pointers to 802.11b/g amplifiers? Most of the results I get Googling are for the more "traditional" designs (from RF component vendors, booksellers, etc.) -- I didn't see any homebrew 2.4GHz amp schematics aimed at the casusal WiFi enthusiast.

> ... and while they mention the microwave oven--I don't think anyone is
> attempting it!!!

Someone claiming they can take a magnetron from a $59 Wal*Mart microwave oven and turn it into a reasonably linear power amplifier has a pretty poor understanding just what it is that (1) amplifiers and (2) magnetrons from cheap microwave ovens are meant to do. :-)

In a production model receiver? Mais non. That's
not a design prerequisite, never was, not even with
the Rhode & Schwarz designs featuring very high
3rd IP specifications.

I've been IN such situations on aircraft installations
where the potential RFI was much stronger than in ham
DXpedition or Field Day setups. The work-arounds to
make the receivers operate is NOT a design criteria,
not in avionics-oriented design plans.

Possibly, IF and only IF the antenna IS connected
to the "backplane" (or motherboard). Why must it be
so? Look at the PC. Sound cards have their audio
input (at microphone levels) on a separate connection).
No interference doing that.

>In non-contest sites large wire or log-periodic antennas can collect a
>quite large signal voltage (in the order of 0 dBm, 220 mV or more).

Perhaps, but that still isn't a design criterion for
present-day ham receivers.

>Also if the final IF is within or below the receiver tuning range and
>a diode ring mixer is used as the SSB demodulator with +7 or +17 dBm,

Yes...but that was a problem a half century ago, too! :-)

>Even the SDR is going to need some switchable front end band pass
>filters in order to survive in the hostile RF environment these days
>with a lot of strong signals even in ordinary sites.

Diode switching. My two-decade old Icom R-70 has that
to select approximate octave-bandwidth bandpass filters
to cover 50 KHz to 30 MHz. Has its own little PCB,
probably because every single L, C, diode, and resistor
is included on that board...no shielding except from
the side wall of the cabinet and part of the cast frame.

I've had that little receiver within a city block from
AM BC station KMPC running 50 KW into its towers. Worked
fine with a temporary long-wire antenna despite the RF
around that station.

>In transceivers, there would be several points that would need
>switching.

Of course. That's what was done two decades ago.

>I used the CANbus as an example, since the cable can be tens or
>hundreds of meters long depending on speed and thus, it could be used

>same controller could control the antenna rotator, command the antenna
>preamplifier to bypass mode, turn the transvertter into transmit mode,
>select the VFO frequency for transmit (in split operation) and finally
>turn the transmitter on.

Right, no problem...except for the individual ham
installer who then has to set up the "program" to
do all those things. Can they? :-)

I think a better approach is something like SGC does
in their automatic antenna tuners. They add a
frequency meter function to their tuner micro-
controller, a small section of Flash memory to
hold data, measure an RF input, adjust the coupler
switches to compensate for VSWR, then record that
data in memory. Any future frequency close to the
recorded memory can use the same settings.

Near-ultimate in modularity is thus achieved. Needs
only DC power to operate and doesn't care what kind

of transmitter is connected to it...as long as its in
specification for power and frequency. Absolutely
"plug-and-play!" :-)

>> What is lacking is STANDARDIZATION.
>
>This is definitely a big problem.

Yes and no. :-) It's like a recipe for "tiger
soup:" "First, you have to catch a tiger..."

In a similar way, there must be SOME idea of
what kind of control range, modulation, etc.,
etc. would be expected...and for what radio
service. The FCC in the USA can't yet come to
grips on that, nor has industry made much
progress outside of their own product lines.

Right now, it is more like Pandora's Box.

>> That can't be worked out in newsgroups,
>
>A newsgroup is a good place for open ended discussions between people
>with experience in quite different fields.

I agree. But, like the infamous "John Smith,"
it can be infiltrated with someone who doesn't
have either the experience or the courage to
use his/her real name. Raises the noise
level enough to make some go QRT for a while.

>Writing a formal specification may require some formal organisation,
>but on the other hand quite a few successful RFCs in the IT sector are
>written by a single person or a small group.

Ahem...that INDUSTRY specification is going to
range considerably farther than some small group
within one company. As to IT (Information
Technology), I've not seen ANY industry-wide
softwares which extend beyond corporate levels
and that's been for the last three decades.
LANGUAGES not counted there.

>> and willingness to compromise
>
>That is the problem in formal committees, in which most delegates from
>various vendors have large commercial interests in the subject and in
>order to be able to produce even some kind of standard, all features
>from various vendors are included.

I'll just cite the ARINC standards which are
generally used internationally for all civil
avionics, from radio to radar, radionavigation

systems. ALL the interfaces to every avionics
box and the physical shape and mountings. NOT
a big commercial venture in terms of profit.
If you've been able to read the verbatim minutes
of ARINC meetings (I have), then you would see
that it can be done.

ARINC = Aeronautical Radio INCorporated, once a
radio communications provider for airlines,
later evolving into a combined industry-government
central standards organization for civil avionics.
[they have a website, BTW, but the documents are
horribly expensive now...]

Only "three?" :-)

>That's pretty low
>volume to undertake radical development. We're probably lucky that we
get

>any new features.

Tsk, tsk. Having first started to legally transmit RF (on HF) in 1953, I've been watching the progress of most ALL radio technology for a mere half century. ...and seen the DESIGN as well as manufacturing shift to Asia. In Japan alone, there are at least FOUR corporations doing HF radio design, not just three. USA designers and manufacturers ARE there NOW, but none of them are Collins, National Radio, RME, or Hallicrafters. [only Collins Radio is left of all of them and they do NOT make ham equipment]

Take FREQUENCY CONTROL, an essential thing for stable SSB work on HF. The PLL took care of that nicely with - perhaps - Icom leading the way to get 10 Hz increments at quartz crystal control. To save some costs, the three major players (Icom, Yaesu, Kenwood) switched over to DDS (Direct Digital Syntheses) after trying out 'fractional-N' PLL synthesizers.

Asian DESIGNERS and manufacturers were there first with the LCD screens to show analog information in digital form. They may also have been the first to include microprocessors and microcontrollers to act as control-display interfaces, saving hundreds of store dollars per unit and eliminating mechanical couplings almost entirely.

Try DSP (Digital Signal Processing). That's in the ham gear of TODAY. Not a "first" in amateur rigs since it was first introduced on consumer electronics. But, it is THERE. Today. [I could go on...:-)]

100K production lots are "low volume to undertake radical development?!?!?" Oh, my. Let's look at that in more detail...say at 10K production runs. Try, for example, with an average price of $1000 per HF ham transceiver. Sell price dollar flow would be $10 MILLION. Designer-manuafcturer dollar flow is roughly half that, $5 MILLION to split off many ways: component costs, burden, advertising, profit, losses on defects, to name the major items. Perhaps $500K can be the amount amortized for the actual R&D. At $50/hour in estimated engineering salaries-plus-burden of Japanese companies, that's 10,000 man-hours for the design-development budget. A team of 10 then has 1000 hours average to do one task. At 50 hours per week, that's 20 weeks to get what is largely (in practice) the production side of the house going, at least a third of a year.

But, very very few designs are "brand-new" in ANY catalog. The majority are revisions of the older models, perhaps using the same "universal" cast framework-support and cabinet but needing only the front-panel face-lift. The time - at 10K run lots - is plenty long enough to come up with the "new improved state-of-the-art" things that glow triumphantly (in purple prose) from the ads in QST. :-)

Do the big makers have "single model" catalogs? No. Not even the medium-sized ones. All have MANY models and branches...such as the Handheld transceivers. The HTs plus VHF/UHF base stations tend to be the company bread-and-butter items, sold - in almost the same features as for hams - to industry, business, and government. With some revisions of the basic structure those become "amateur radios."

On the down side, the HF bands are NOT a big-ticket item for communications as they once were. Today the RF world is deep into cellular telephony for sites and providers, and some for users (at companies with large production lines and consumer marketing structures). The world of communications has moved UP and over that mythical, artificial dividing line of 30 MHz.

Michael, don't let this POSEUR bother you. That
anony-mouse "John Smith" hasn't been there, hasn't
done it. He wants to be "Instant Guru" and wants
a "rep" without doing any work for it. From what
he states - all in generalities, no specifics -
he can't think things out close to necessary detail.

You were right to "plonk" him.

> You have your head up your sorry ass, and I'm through wasting time

>design when you compare the Apple II to a real design project. You
need
>to get an education in design and stop trying to blow smoke up
>everyone's ass.

Way to go! :-)

At some other time I wouldn't mind having a friendly
argument with you on the Apple][...but not with this
anony-mouse hanging around trying to intrude and
smoke up the place. I still have my 1980-purchase
Apple][+ and had a lot of fun with it...including
lots of calculations (Applesoft had 10-digit
accuracy with 5-byte FP variables, muy better than

4-byte single precision). I've gone into the hard-
ware and analyzed it thoroughly, scoped it, written
it up...submitted it as a manuscript only to find out
Howard W. Sams was already in production on a similar
book! :-)

In many ways, the PRODUCTION version of the Apple][
was the forerunner of the IBM PC out of Boca Raton.
But designed (or rather re-designed) about two years
prior to the IBM PC. Uncanny similarity between the
two in basic structure, expansion slots, and - yes -
"open architecture." PRODUCTION planning went into
the][and it wasn't much like the original board-
only Apple.

But, the][on up to the Apple //gs were terrific RF
generators! :-) By contrast, a similar structure
using only three main chips (CPU from Western Design,
64K EPROM, 64K/128K Static RAM) can be very nice and
quiet RF wise because of the internal transistor
structures in those chips. [I've already done a
preliminary breadboard setup to verify that] Such a
controller system can adapt itself to many kinds of
"radio controller" applications without any of the
RF coupling problems. It's been done before by the
big three in Japan using older microcontrollers in
many different transceivers, all without disturbing
the receiver or the transmitter specifications.

Too many of the older hams are oriented towards a
"legacy radio" structure...mostly analog. That
just doesn't adapt to "plug-and-play" ease of adding
or modifying an SDR. Trying to use a common PC as
a "model" for an SDR is a bunch of nonsense. The
"bus" and "interface structure" is an analogue only
the broadest sense of the term. Doesn't apply,
either technically or organizationally.

As far as "John Smith" goes, he's gone. He is just another hopeless
wanabee who doesn't understand anything about the real world.

Len, I have worked from DC to 11 GHz on commercial designs and anyone
that thinks any design is easy just doesn't have any idea what's
involved. Its one thing to hack together an almost working prototype,
but its a whole different animal to design from the bottom up to meet

set specifications, make sure the components will be available, and if the unit is to be sold, to make sure that it will clear the FCC, UL and other requirements. If you decide to manufacture the equipment for sale outside of the US you have the CE certification, and ISO 900X to deal with.

If i had the money I would put together a nice kit to sell, but other needs come first.

I designed my first receiver in the late '60s while I was still in high school. It was mostly tubes, and a modular design so I could replace sections to update the design. I had it almost done when I was drafted. When I got out of the service my family had torn down my workshop and the prototype and all my paperwork was gone. I learned a lot about receiver design at Microdyne, and their telemetry receivers were all modular. They had to be, because a customer would need something special, so we would charge them to redesign a module or two to adapt a standard product, rather than to design a complete receiver.

It would be interesting to set up a group to develop a modular system, but getting people to agree on the specs can be more work than the actual design.

2461. GDO sensitivity

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-05-12 10:17:40 UTC
From: Markus L <uo9oew@lnubb.pbz>
Message-ID: <w3Gge.12$ae.3960@ns2.gip.net>
Source record: 18994

Am planning to build the GDO described by SM0VPO at
http://web.telia.com/~u85920178/use/gdo.htm using a BF245 FET (BC245
mentioned is a typo). What parameters determine the sensitivity of a GDO?
Will the sensitivity go up or down when increasing the gain in the
oscillator stage? Intuitively I would say the gain has to be just high
enough to guarantee a steady oscillation, but maybe I'm totally wrong.

Actually I agree. I was thinking of cutting that in half due to inactive
hams and got in a rush and forgot to do that.

| Howard W. Sams was already in production on a similar
| book! :-)
|
| In many ways, the PRODUCTION version of the Apple][
| was the forerunner of the IBM PC out of Boca Raton.
| But designed (or rather re-designed) about two years
| prior to the IBM PC. Uncanny similarity between the
| two in basic structure, expansion slots, and - yes -
| "open architecture." PRODUCTION planning went into
| the][and it wasn't much like the original board-
| only Apple.
|
| But, the][on up to the Apple //gs were terrific RF
| generators! :-) By contrast, a similar structure
| using only three main chips (CPU from Western Design,
| 64K EPROM, 64K/128K Static RAM) can be very nice and
| quiet RF wise because of the internal transistor
| structures in those chips. [I've already done a
| preliminary breadboard setup to verify that] Such a
| controller system can adapt itself to many kinds of
| "radio controller" applications without any of the
| RF coupling problems. It's been done before by the
| big three in Japan using older microcontrollers in
| many different transceivers, all without disturbing
| the receiver or the transmitter specifications.
|
| Too many of the older hams are oriented towards a
| "legacy radio" structure...mostly analog. That
| just doesn't adapt to "plug-and-play" ease of adding
| or modifying an SDR. Trying to use a common PC as
| a "model" for an SDR is a bunch of nonsense. The
| "bus" and "interface structure" is an analogue only

| the broadest sense of the term. Doesn't apply,
| either technically or organizationally.

2469. Need Murata CFJ455 K12 filter

Newsgroup: rec.radio.amateur.homebrew

Hello,

I need a Murata CFJ455 K12 or CFJ455 K5 ceramic filter. These are
455khz filters you would pull out of a transeiver to upgrade filters
such as with Inrad filters etc.

Thanks,

Rick KC0HH

Rick -

The Yaesu FT-817 and Icom IC-703 use the MuRata CFJ455K ceramic filter. So a Collins mechanical or Inrad upgrade like shown at W4RT would qualify
http://www.w4rt.com/obf/OBF_IC-703_Manual.pdf

I looked at that. It is the CFJ455K 15... The K12 and K5 need to
see a 2k input and output. I am not sure what the K15 filter uses. I
am trying to resurrect a TS-830S. I received it sans any filters.
These are the stock 455 filters. I need to get a filter in there to
see if it still works. I really did not want to sink a bunch of cash
in a Collins or Inrad filter and then find out the radio is not
worth fixing.

>
> Markus HB9BRJ
>
>

You are on the right track. As you probably know, the "grid" dip is a result of the resonant circuit drawing energy from the oscillator. The closer the oscillator is to stalling the more sensitive it will be to dropping out when the dip occurs. The problem is that other factors, such as proximity to metal objects, other spurious resonances, etc, can also stop the oscillation. In practice the trick is starting with the unit near the target circuit and keeping a high enough oscillator gain to be well above the threshold and sweep the unit to see a small dip. Then move the coil away from the circuit while reducing the gain and sweeping to see that the dip frequency stays approximately the same. The dip should become deeper. At some point the gain will be at the limit of oscillation and this is the lightest coupling to the circuit, and the most accurate.
Once you have it built you will find that it is really easy to get a feel for the operation, more so than a few sentences can convey.
This reminds me that I haven't used a GDO for a few years, having accumulated a bunch of nice test equipment, but somewhere in my shed is an old Lafayette 6CW4-based GDO which over the years has helped me get a load of homebrew gear on the air. That's a lot of QSOs thanks to a simple piece of equipment!

If you can cobble a way to patch in the Murata CSBLA455KEC8-B0, just
to see if the rest of the radio works, Digikey sells them for less
than a dollar.

The specs are on page 41 of this catalog:
http://www.murata.com/catalog/p17e14.pdf

Sorry Tim, I beg to differ....

True, the tank circuit frequency gets dragged around by "hand" capacitance, but the place where ths effect is felt is almost invariably the capacitance between ANTENNA, CHASSIS, BODY and GROUND rather than direct hand-to-LC.

Better grounding is nearly useless, unless you bolt the chassis to a very good, high capacitance ground - e.g. you bolt it to a steel bridge on a ship. But even then, your hand and body may introduce a change in antenna-to-ground capacitance -> back to square one!

An extremely loose coupling will reduce this effect, but it's very hard to pull off while keeping an efficient energy transfer.

It's better if you use an active buffer stage. Nowadays you rarely see solid state regens without a buffer, and the reason is not signal levels - it's that capacitance decoupling through an active device can be very effective, making both frequency and regeneration more controllable.

Another trick, less practical, is to move the antenna far away, and feed it via coax. In this case, grounding the coax somewhere along the run (at zero impedance if you route the coax by a good RF ground point) is very effective at stabilizing antenna capacitance to ground. In this case you will indeed see almost exclusively the effect of hand-to-LC, which won't amount to much and can indeed be fully killed by a shielded enclosure.

But that will work on transmit, too. The only difference is that
you will have a DSB signal rather than an SSB signal.

If you can hear things, and you can transmit a signal, surely
the rig is in good enough state to warrant tracking down a suitable
filter.

Unless it is an ugly duckling .. TS-830 repair should be straight forward

I think most of the Murata filters are either 1.5K or 2K input and output

In the second RX of the Yaesu FT-1000(D) and the FT-1000MP you will find a
Murata 455 kHz ceramic filter.
This will be the Murata CFJ455K '15', '13' or '5' filter.

COMPUTERS - ELECTRONICS - HAM RADIO - COMPUTERS - ELECTRONICS - HAM RADIO

FLEA all SUMMER at MIT
Sunday May 15th 2005
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take
place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >2000 cars!

Buyers admission is $5 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $20 for the first and
$15 for each additional at the gate.

The flea will be held at the corner of Albany and
Main streets in Cambridge; right in the Kendall
Square area from 9AM to 2PM, with sellers set-up
time starting at 7AM.

SEASON PASS + Advance Seller Discount

A sellers discount season pass is available which
offers a 30% discount. By prepaying you get a
discount and earlier admission. See the registration form.

*** Attention Sellers ***
Prepaid vendors.. Season Pass or monthly,

will be admitted FIRST.
Separate lines will form prior to gate opening
for prepaid and nonprepaid vendors

!! RAIN or SHINE !! Have no fear of rain, a covered
well illuminated tailgate area is available for all
sellers (6'8" clearance).

Talk-in: 145.23- (PL 88.5) W1BOS/R and
W1XM/R-449.725/444.725 (PL 114.8/2A).

Sponsors: MIT Electronics Research Society

Body handling: HTML body converted to readable text

Decades have brought us moon landing, mars landings,masers, lasers, lets, fets, mosfets, computers, etc...

But the shape of radio equip. has remained virtually stagnant.

One "innovation" would be to just copy what the IBM clone has taught us.

Build a radio of "cards." Just like the computer, a standard case which you can plugin various power supplies, frontend board "cards", intermediate board "cards", buffer amp board "cards", IF board "cards", audio board "cards", xmitter board "cards", final amp board "cards", etc....

One radio case can/could virtually be any radio you can imagine.... new design in a frontend? Plug in a new front end "card", new audio offering? Plug in a new audio board "card."

Someone really should get off a dead duff somewhere and DO IT!!!!

Kinda makes ya wonder why not? Doesn't it?

Warmest regards,
John

Not sure how restrictive your idea is, but it ain't new.

You can even find the odd receiver on e-bay with cards for each function plugging into a bus - try Plessey for example. Even the ancient Davco DR-30 and the first solid-state heath transceiver (SB401 IIRC) used plug in RF, IF etc cards.

Several modern scanners, especially portable ones have a selection of optional plug in cards for things like, extra channels, digital decoders, tone squelch etc. etc.

I had an early Yaesu VHF/UHF receiver which had an optional plug in card video decoder. My Kenwood R-5000 has provision for a plug in VHF front end.

I used to have a RACAL receiver, old enough to be antique now, which used plug in front ends for various coverage options, and I seem to recall it was a fairly common idea in those days.

Dave

Goodness knows why, but I was assuming a nice coax feed from the
antenna. While that normally makes sense it can't be assumed with a
regen, I suppose.

If you're using the regen to receive CW or SSB you should be using an
amplifier anyway.

Just a quick thumbsuck...

The only "significant" HF users these days are:
Shortwave broadcasting - except for being HF, their equipment has nothing in common with ham rigs.
Military - "Black box" rigs with a minimum of knobs&buttons - most also feature secure spread spectrum - so not much commonality with Ham equipment here either
Then there's Hams - most of us want the maximum possible bells, whistles, knobs and buttons. Hi tech features with everything" user adjustable/selectable.

Maritime and Aviation users are moving / have already moved to satellite for "longer than VHF range" comms.
Other commercial HF users are very few and far between.

So it really is quite amazing that we get the rigs we do.

My experience of "professional" 2-way radio users: I'm a member of the Police Reserve here in South Africa (quite similar to military reserves).Not a single one of them (30-40 people) has a clear understanding of the concept of frequency. All they (need to) know is how to select channel number and adjust the volume - their radios only have those 2 knobs. They also know not to start talking before the beeps have stopped. That is the sum total of their "technical" radio knowlege. (No wait! - Some of them also know how to swap a HT battery pack.) Everything else: channel programming, CTCSS, repeater offset, etc. (internal controls) is done by the techies at the provincial headquarters.

Hi, all concerned:

If you have a homebrew and/or kit project, gathering dust, send me its original intention, a
picture if possible, its weight (for ground shipping estimate to 45251), and what you'd
like to get for it, and maybe we can shake hands and do business.

Tubes or transistors -- doesn't matter.

TIA and

A problem in discussing things in diverse groups is
that the vast majority does NOT have such experience.

[there's a short pause while a few regulars become
overheated with indignation... :-)]

The vast majority get their "experience" from READING
about it - AFTER all the development fuss and fury has
been done. If the writers and editors are good at words,
they create the fantasy that the reader has been there
"too." [there's a whole lot of 20-20 hindsight going
on with those readers]

> Its one thing to hack together an almost working prototype,

You said it, brother! :-) The PR splashes and articles
in QST just do NOT go into days, weeks, months, week-
ends, deferred days off, sweaty times on the bench
with "stubborn" things (finding out little annoying

things one might have forgotten to include) or finding
that a component is NOT in tolerance, "fix" days in
having to work around a problem caused by someone ELSE
not doing their job quite correctly and being stuck
with finding the cure. Neither does it include some
total fascination in seeing a creation come to LIFE,
bit by bit and working AS designed, the pride in one's
self for having done so (a quite kind, most
satisfactory, adding one more mark on self-confidence).
It is a satisfaction in having been given an arduous
responsibility and achieving success in meeting it.
Besides, it can be fun! :-)

> It would be interesting to set up a group to develop a modular
>system, but getting people to agree on the specs can be more work than
>the actual design.

Actually, in this rather lengthy thread, which has no
real consequence to hobby electronics, there really
wasn't any "need" to "develop a radio specification."
It was a mild rant by an anony-mouse who hasn't been
there in real life and wanted to become some kind of
newsgroup age Keroac a la four decade old "protest"
movement.

"Putting together specifications" has been done for
centuries. It is never easy because too many chafe
at "being told what to do" or expect that every spec
is "perfect, something that must be adhered to at all
costs!" Those kinds of critics haven't had to BE
there, working it out daily, weekly, monthly in a
sea of contentious differing-opinion souls all of
whom consider themselves "right." :-)

I doubt (sincerely) that there's any NEED to have
"a radio" modular. The 'radio" already has been a
system built of modular circuit blocks for decades.
All those blocks have to work together to make the
"radio" work and the "radio" designer's task is to
integrate those modules, make them work together.
[replace "radio" with "any electronics" and the
same thing is true]

What seems to be operative in this thread is that
some look at a PC and its very-mass production
"module" pricing and the "plug-and-play" concept
and sales phrase popularized by Microsoft and think
it applies to all electronics. It doesn't. Those
same imaginerers probably would get totally lost
in trying to figure out how a "simple" plug-in card
on a PC works; all such cards nowadays are little
subsystems, complex, a few being little "computers"

all by themselves (if using a microcontroller).
They only look at the overall card specifications
and THINK they "know all about it." [all they've
done is to memorize some data items about the
product...well after the development tasks' end]

Three decades ago, radio amateurs got a taste of
"radio modules" in the burgeoning use of handheld
transceivers. A single Tx-Rx that could be held
in one hand, complete with antenna. A full radio.
(first done about 1940 for the U.S. Army and
dubbed "the handie-talkie") One "module."
A stand-alone communications tool. "Integration"
of that module didn't need other electronics.

Now with Software-Defined Radios, non-thinkers
want to make those like the millions of cheap
personal computers. Most don't know the basics
of either receiving or transmitting radio signals
or how to handle modulation, yet they want to talk
AS IF they did. :-)

[more righteous indignation by some readers here
as they chafe at the bit wanting to vent against
the statement above...heh heh]

SDR is a terrible problem for the FCC in its task
of regulating technical characteristics of civil
radios...and will be for all other radio regulating
agencies internationally in the immediate future.
A very different problem.

The thing is that SDR is ALREADY HERE and has been
for decades...BEFORE the advent of the micro-
processor and microcontroller. [that's a whole
new area of discussion whose birth might have
been in the transition of the regnerative receiver
with audio amplifier into Ed Armstrong's "super-
heterodyne" right after World War One] That the
modern "radios" use "software" (actually digital
control signals) instead of hard-wired manual
control operation lines doesn't matter to the
"radio's" circuit blocks. Those circuit blocks
still have to be integrated to make the whole
"radio" system. Their theory of operation has
NOT changed.

>--
>Former professional electron wrangler.

I'm still doing that...but not at regular office
hours...and prefer my own lab/workshop area. :-)

Well my 30 year old project isn't for sale, but you can build one for
yourself if your really wanting to have a useful project.
I have posted on my web page a
http://personal.atl.bellsouth.net/m/e/metacalv/Directionalcoupler.html
Directional Coupler.
What is really a homebrew Watt meter like a Bird watt meter only the slug is
not changeable for my set up.
I would guess some changes could be made for changeable slugs. I built
mine just for 2 meters and has served me well
and is still in good working condition. A useful 30 year meter might even
be hard to have for a commercial meter.
This would seem to be as inexpensive and challenging a project as one might
reasonably ask for.

Good luck. 73 WB9SMX Gary

Still looking for some pointers and/or advice on current AM transmitter design. There doesn't seem to be much out there apart from the "pirates" who are building SW transmitters around 5W or so...(e.g. the "Grenade" QRP transmitters and similar designs)...

Is AM ("Ancient Modulation") considered dead and therefore there are no links/publications worth reading?

Bill

Source record: 18931

Just run the output of any audio source of ~5 watts into a "modulation transformer" and have the B+ to the transmitter pass through its secondary...

You can also construct an audio amplifier whose output power final "modulates" (perhaps the B+ from the audio amps final transistor/tube) the B+ to the xmitter... etc... ssb is by nature 2X-plus more efficient... fm supports greater sound quality...

I think detail about it is skipped simply because it is so easy to affect....

Warmest regards,
John

2500. FCC BUST IN TEXAS

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-05-14 08:57:57 UTC
From: willfull_buck@yahoo.com
Message-ID: <1116061077.163644.153230@g47g2000cwa.googlegroups.com>
Source record: 18933

Hey Folks,
Kinda down at the moment, our college radio station got busted by the FCC. Here a list of the stuff that was hauled off:

NRG PLL-PRO 3 20W TRANSMITTER
NRG 220 WATT RF LINEAR AMPLIFIER
NRG PRO III STEREO CODER
NRG PRO III STEREO LIMITER COMPRESSOR
DAIWA CN-101L SWR+POWER METER
COMET CFM-95SL 5/8 WAVE ANTENNA
50 FEET OF LMR 400 COAX
KENWOOD R-1000 SW RECEIVER (my fathers old short-wave radio?)

The really weird part is that we WERE NOT transmitting at the time of the raid. One of the agents tolds us that they traced us through a purchase order from Broadcast-Warehouse! It's true that we bought a 150w amp from broadcastwarehouse.com a few weeks ago. How did the FCC know about that?

Anyways, we will rebuild the station and continue to fight the globle interests of the MEGA-MACHINE.

DEATH TO THE MEGA-MACHINE!

Sounds like a candidate for one of the mentally impaired neo-Nazi groups.
The station was either unlicensed or not authorized for the power they were
running. Given the immature post I also assume that the content wasn't very
nice.

LIFETIME COLLECTION ANTIQUE RADIO AUCTION Sunday May 15, 2005
Warren Michigan

Sunday May 15, 2005 11AM
(3) 10x 20 UNITS! (3) 10x 20 UNITS!

The Lifetime Collection of a John Cottec Local Collector and Repair Technician to be auctioned off to the highest bidder!

Highlights include Vintage Antique Tube Radios. Floor Models as well as Tabletop. Antique Speakers, Stereo Equipment, Tuners, Over 1,000 Tubes in
original boxes, Tube Testing Equipment, Oscilloscopes, Tube Amplifiers,
Troubleshooting guides, (5) File Cabinets of Sam's Photo Facts Schematic books,
Many Boxes of Parts, knobs, Caps, Resistors, Controls and other parts of many
kinds, Turntables and Record Players, Record Albums, 8-Track & Reel to Reel
Tapes. Some radios are in working condition and some are in need of restoration.

Some of the brand names include... Sparton Blue Mirror Tabletop, Fada Bullet, Lafayette, Scott, Fisher, Hickok, Kenwood, Heathkit, Stewart Warner, Delco, Capehart, Motorola, Bogen Presto, Acoustic Research, Zenith, Harman Kardan, Recordio, Jans Zen, Stromberg Carlson, Detrola, Dewald, Marantz, Goplana, Philco, Eico, Bic, Atwater Kent, General Electric, Roberts, Superior, Telefunken, Kingston, Dual,
Blonder Tongue and Air King to name a few!

The auction will be held at the Safety Mini Storage facility located at 2420 E. 14 Mile Rd. in Warren, Michigan.

Preview the auction from 9AM. Auction will begin promptly at 11!

The Records will be sold 2 for a Buck during the pre-view!
markblondy.com for more details and photos!

Poor soul does not know that traditional radio is dead
(Wall Street proclamation by analysts and investors earlier this week -
go read TheStreet.com).

Why?

Internet Radio stations (streaming audio), XM and Sirius Radio (Howard Stern
and others) and new digital "HD" format for over-air stations
Infinity Broadcasting announced earlier this week that WUSN-FM 99.5 HD-2 in
Chicago will be the first continuously programmed HD Radio multicast channel
by a commercial broadcaster..

and technology marches on .... like demise of end of 8-track and cassette
tapes.

Hello,

If SSB only may be a beginning ...
if French text may be understood ...
if a very good description, with good schematics can agree ...
then go to :
http://perso.wanadoo.fr/f5cau/xver144/page_xver.htm

and download pdf :
<xver9hx.pdf> 1.6 Mb

This VHF SSB transceiver was design for substitute of IC202 for down conversion in a SHF station. The author, Andre Jamet, F9HX, is known in France for his good job and papers about it.

73,
F6AWN

Hi Rama,

I've not seen a complete design listed anywhere, but, if you find one, or want to ADD (say) an LNA, or some such, a high power PA?, to it or what you have now, I will try to help you with a design. I don't charge hams for help, BUT, if I were to drive thru your city, and you were to offer me "lunch" or a pizza at a local pub, well - that's different! <g> I can be "had." <lol>

Take a peek at my "commercial" site. I hate to use that name as I built it all myself. To me "commercial" is something like Bill Gates & Microsoft. I prefer to refer to my site as a "personal" site that happens to sell good RF tools, (at LOW cost), that I've created, over the enjoyable years I was active in ham radio starting in 1953.

Anybody ever hear of a bootleg radio station called WCPR? (aka WFAT).
They were on from Brooklyn NYC in the 70's.
They hung out on the upper end of the AM BCB (1650 ish).
Their equipment was an old Collins transmitter. I don't
remember the model, but it had plug in coils to change bands,
a slug tuned vfo (actually wasn't a vfo, but could be set
via a screwdriver to frequency, no crystal used), and used
a pair of 807's in the final modulated by 4 6L6's in push-pull
parallel. Using a long wire flat top about 200 feet long between
two 23 story high apartment buildings they were heard across the pond.

A friend of mine gave the equipment to two college kids that
put the station on the air using their stereo as a mixer
panel. They also used phone loop-line numbers to take over
the air phone calls without giving out their own phone numbers.

While I don't support illegal activity (but do support revising the law--and the publics right to access expanded spectrum), as a teenager I loved to search the SW bands for pirate stations--I still hope the youth find as much pleasure as I did in that pursuit--somewhere...

Especially interesting were the "Pirate ships", ones with xmitters onboard... I would listen late into the wee hours... still managing to get to school the next morning...

Warmest regards,
John

| Anybody ever hear of a bootleg radio station called WCPR? (aka WFAT).
| They were on from Brooklyn NYC in the 70's.
| They hung out on the upper end of the AM BCB (1650 ish).
| Their equipment was an old Collins transmitter. I don't
| remember the model, but it had plug in coils to change bands,
| a slug tuned vfo (actually wasn't a vfo, but could be set
| via a screwdriver to frequency, no crystal used), and used
| a pair of 807's in the final modulated by 4 6L6's in push-pull
| parallel. Using a long wire flat top about 200 feet long between
| two 23 story high apartment buildings they were heard across the pond.
|
| A friend of mine gave the equipment to two college kids that
| put the station on the air using their stereo as a mixer
| panel. They also used phone loop-line numbers to take over
| the air phone calls without giving out their own phone numbers.

So you're saying that there's no info because it's far too simple - so why bother to write it up in a text or app note?

Surely there is some small amount of "finesse" involved - whether it be in the implementation of the modulation transformer or in trying to get the optimum modulation levels in general. Nobody has covered this in a text?

I'm sure I could come up with some brute-force approach in doing the high-level modulation using a kludge transformer (the "grenade" guys are using simple line level transformers run "backwards")...

Either there's a more "scientific" approach to this or, as you suggest, it's always done empirically??? Just wondering......

Did you google for "plate modulation" or "grid modulation"... you should
turn something up there... even if you come across info for tube equip.,
the info is still just as accurate for transistor equip....

How about a trip to a used book store in your area to see what is available?

I see your point, I didn't say that correctly...

You are right, the information should be more available--its missing may
just be a lack of interest or anyone building am equip these days...

The pirate group and "freebanders" have groups, but you have to know someone
to be allowed into their discussions... I know "hidden chat rooms" exist on
IRC... but I have never been invited...

Warmest regards,
John

I suspect there's just not much interest in VHF AM. At least the HF AMers have a world to find contacts in. Contacts on VHF are pretty much local, and the probablility of finding a fellow AMer on VHF locally are vanishingly small.

Indeed, why would someone use AM on VHF? If you don't like the sound of sideband, use FM. If you simply want to get the message through, use packet. If you want to operate under adverse conditions, use CW. AM has precious few advantages in this day and age.

If you look in old issues of the Handbook, you will find designs for VHF AM gear. If you hang around hamfests, you might uncover a twoer or sixer that might still be coaxed into working. But mostly you will find tube gear from an age when FM was complex and finicky.

But today, VHF FM is ubiquitous and cheap, so any AM equipment is playing to a tiny niche.

And dont forget Aplac:
http://www.aplac.com/

Yes, you have to register, but its quick and free. The free version is crippled, but certainly good enough for Ham use. Lots of really nice stuff, but don't bother trying to get the manuals unless you have a high-speed Internet connection.

Source record: 18851

The last bastion of VHF-AM is aircraft, both civilian and military. The civilian aircraft com band goes from 118-137 MHz. and the military from somewhere around 225 to 400. Those of us who have spent our lives in this little corner of the design world are few and far between.

As to those who say that AM is so simple that anybody could do it, I respectfully disagree. I even DISrespectfully disagree. Trying to amplitude modulate a synthesized AM radio without having as much FM in the output as AM is no mean feat. In the old vacuum tube days with crystals for the synthesizer it isn't all that difficult. However, with digital synthesis and VCOs that will FM at the drop of a hat, it is far from trivial. Shielding to the center of the earth and power supplies bypassed from DC to daylight are the order of the day.

I'm looking for a solid desktop (either pizza-box or mini-tower)
computer case that has an all-metal exterior for shielding RFI. This
is for use around radios etc. I realize that SVGA monitors, mice, and
keyboard leak too, but right now I'm looking mainly at the PC box.

Most of the cheaper cases come pretty close to good shielding, but they
have these plastic filler panels in the drive bays that offer no
shielding and let a lot of RF leak out.

Most of the fancier cases in the computer stores around here have
humongous plastic pieces on the side. I'm looking for all-metal.

Rack-mount server cases seem to be pretty good in terms of metal
shielding all around but I need something for desktop use.

Any suggestions? If all else fails I can just put some perforated
metal over the holes in a cheap case, but I'd rather just buy a good
case to begin with.

Tim.

You could always shield the plastic panels with copper or aluminum foil or screen--etc... (on the inside--out of sight)

What about that gaping big square-foot hole in the side?

> I have even seen an all stainless steel case which is used around
> food

The old "PC Power and Cooling" all-metal-tower used to be good (I think it was available in chrome!), but they don't sell them anymore (probably because they cost several hundred $).

I'm not looking for anything particularly stylish. Just a case without big holes covered by plastic.

Tim.

Personally, I'd place a sheet of aluminum window screen between the acrylic sheet and the case--that way I could still get the effect of looking into the case, and still be shielded...

Other than that, I'd pick the one from their catalog which DOESN'T have the "big gaping hole" in the side... <grin>

Warmest regards,
John

Take a look at these barebones systems:

<http://www.tigerdirect.com/applications/category/category_slc.asp?MfrId=1106&CatId=31>

If the link doesn't work click on "Barebones", then select "Shuttle"
from the brands menu.

My 3.3Ghz seems to broadcast on most frequencies--from rfi in the am radio, fm radio, sw bands, etc... toroid chokes on the phone/modem/net card cables helps a lot...

Warmest regards,
John

> It depends on the computer.

What he said. Usually on all harmonics of each clock in the box, from ~1.8 MHz on up to near daylight -- or at least well past 70 cm., in the case of the boxes here at home and at work. Add in all their cross-modulation products as well, and it starts to look pretty gross. One of these days I'll borrow a spectrum analyzer and see what's coming from where. I know that the bedroom TV puts out a lot of stuff around 3.5-4.0 MHz. and the cable box is pretty noisy, too. Hard to hear DX over all the in-house QRM.

Take a closer look at some of the higher quality cases.

All the cases I have purchased within the past few years have plastic, as you say, over the drive bays, but there is metal behind that plastic. If you want to use the bay you need to pop out the metal. Except for floppies, the drives generally have metal behind their plastic faces, too.

More important is the scheme for attaching the sides. Those little drive holes will let some RF out, but long, narrow gaps in the side let out a lot more. Most recent cases seem to have fairly elaborate schemes to be sure that the sides don't leak.

I can't believe many of the mass marketed cases actually make it to manufacturers who need to be certified, but the lengths they go to ensuring RF shielding lately would indicate to me they are getting pressure from somewhere.

As best I can tell, the case isn't nearly the problem the wires are, but even there, it seems like the newer stuff is pretty well behaved. My radios are pracically surrounded by computers and no noise anymore. Used to be a real problem but as the computer equipment has gotten newer, the interference problems have faded. I can still hear my Ethernet on some bands, but I have a pretty ancient hub. Once that gets replaced I suspect the ethernet problem will disappear, too.

FYI:

Some plastic used in cases has a "flash" coating of aluminum
(sputtered in a vacuum chamber). While the metal is extremely thin,
just a few microns, it is enough to provide RFI shielding.

Obviously not as good as solid metal for shielding, but good enough
for many uses. Check out what sort of plastic before assuming it will
not shield.

Happy trails,

If you buy a brand name computer it meets some prety good FCC specs
for emission. IMO if you are carefull any good all-metal case will
produce an EMI-tight case.

Have you got a HF rig? A lot of homebrewers use 10m-2M
transverters. I use my homebrew HF rig to drive a homebrew
transverter and 4CX250B linear.

Have you considered trying an old used HP computer case, one that was used by government? My Linux box is an HP Kayak XA (Pentium II 350 MHz) that has a Tempest-certified case. It was used by the Canadian government for classified work and it was part of a lot that I bought from Crown Assets Disposal. I expect that anything similar would satisfy your needs. (My Linux box does't need all that shielding but why bother changing it?!)

This is very true. A typical SVGA copper cable puts out all sorts of hash (as well as the monitor!). And lotsa junk is radiated and conducted out by the power supply cable, even for the "best of the best" PC clone supplies.

I've discovered and/or engineered some workarounds, consisting of going to optical fiber instead of metal whenever possible. But my converters are usually outside the PC case so this doesn't completely eliminate the radiation from copper cabling.

I'm starting to think I should just sit inside the Faraday cage with my computer, and put all the radios outside!

Tim.

They "lumps" found on many power and data cables are ferrite cores
that attenuate the RF hash that leakes out on the conductors.
Building an RF-proof case is trivial if you don't need any
peripherals. RF comes out on the wires.

Look at a copy of the Ham Radio _The ARRL Handbook for Radio
Communications_, in any decent library or bookstore. They cover RFI
solutions.

Do you have an EMI problem ?

<snip>

I can certainly see your point and I agree completely - insofar as it applies to general applications. My interest is in the aviation bands where AM is very much alive and well (and required). There's probably about zip-nada-squat of interest happening in amateur VHF-AM for the reasons you mention. But there was certainly some interesting traffic on the airband frequencies here in Washington the other day when that nitwit in the Cessna came breezing in....!!! 8-)

This is what I'm discovering. Not only are the people involved few and
far between but so is much of the documented background material
anyone new to the scene might rely on for help....8-(I hope some of
the old-timers will scribble some of this stuff down while they're still
around!

As for the "simplicity" theory - you've hit it spot on with your following
comments. For example, roll-your-own VCOs are only a few bucks
and pretty easy. Off-the-shelf Minicircuits types (e.g. POS-200) are
only a few bucks more. But it sure is interesting to note that Minicircuits
has a new line of VCOs *specifically* for "aircraft communications"
with an asking price of nearly $50 (yipes!)... The difference - VERY
low phase noise.

Apparently there are quite a few variables in implementation of these
"simple" designs - and what you can hear out there on the band is all
over the map. The difference in perceived quality between the "good"
radios and the really "rat-s**t" radios is amazing - and that's listening to
aircraft under identical conditions (for example over the same VOR
checkpoint). Sure leads me to believe that there isn't a set "formula" for
this stuff.......8-)

Help
I've just picked up an HF Power amplifier module, it's still bolted to it's heatsink and looks as though it may be from an amateur or commercial transceiver. the output pair are in a big (0.5"pill) 211-xx package and are marked as ST devices with the numbers 3 100 2 2 on one line and 286M beneath, the driver transistor is in a smaller 211 type package, has no maker's mark but has 31-0021 with 9005 beneath. I've tried searching some combinations but haven't come up with any likely part numbers - I'd appreciate any help in identifying the devices before I apply power and do some tests. The only markings on the board are "BM-1" where the B is slightly above the M and there's a Motorola TIP31 bias regulator - I'm guessing it's not out of a Japanese set because of the device types? The seller didn't know anything about it's background but reckoned a friend had run a test and got 100W out for 250mw in and quoted it as capable of 250W. Any help appreciated.
Thanks
John

Got bad news for you... A homebrew an aviation band transmitter is illegal.
And also you have to be a pilot or air traffic controller to operate an
aviation band transmitter - such transmitter must also pass specified
standards to be legal for use.

A reciever is a different matter of course.
There are quite a few manufacturers that make aviation band reciever kits.

Of course it is - and well it should be!!! I'm interested in the design problems involved. If the results showed that something new, novel or at least in the "better bang for the buck" category could be constructed *and* it appeared to be of some interest to others I'd seriously consider going to the trouble of FCC, FAA, TSO, RTCA, NMEA, STC and whatever other relevant "LMNOP" alphabet drills may be required. But that's quite a ways off and for now this is more of an academic exercise than anything else, mostly because I'm stunned at how little information is actually available. It's a challenge.

> And also you have to be a pilot or air traffic controller to operate an

As noted above.......

I can appreciate you advising caution - but as I previously mentioned (in the original post) I'm well aware of the potential "problems".

> A reciever is a different matter of course.
> There are quite a few manufacturers that make aviation band reciever kits.

But a real shortage of truly well-executed examples - or kits that happen to satisfy my desired set of performance/features.......8-) I've already built a 'couple - and then shredded them one functional block at a time so that, eventually, the result is virtually a clean-sheet design. Sure, it's a lot
of trouble - but entertaining...........8-)

The usage of word "pill" is a "slang" word for RF transistors (bi-polar or
MOSFET) originated in US by non-technical radio operators.

Popular MRF/SRF RF transistors
http://www.rfparts.com/mototran.html

The 211 case style was very popular for bi-polar devices
http://www.rfparts.com/trancase.html

If you are aware of the voltage required (12/13.8; 24/28 or 48/50 VDC),that
would be useful in reducing your search candidates. Specifications:
http://www.rfparts.com/transistorspecs.html

You can inquire with RF Parts if you desire a cross reference - for future
replacement.

Bill,

You won't find much of this information without buying the tech manuals on these aviation band radios and reading about them.

You'll find that the better sounding VHF-AM transceivers do not use simple open loop modulation as has been described ("just hook up a modulation transformer"). That's 1970s technology. We use control loops to linearize the transmitters and reduce distortion. That's one part of the "how do you AM modulate a synthesizer without FM'ing even more" question - the other part is good layout/bypassing practices as someone pointed out.

We modulate at low level (pre-driver - milliwatt levels) with either simple mixers or complex I/Q modulators. The feedback is either envelope ALC, polar or Cartesian.

> Still looking for some pointers and/or advice on current AM
> transmitter design.

One place where VHF AM is still alive is radio foxhunting (RDF).
The comments I've seen in the group so far are filament-based,
hardly usable for a portable transmitter to be hidden under the trees.

A lot of ex-PMR equipment has a closed control loop to reduce the
RF output to what the communication plan allows for (so PMR folk
can use the same kit for customers who need 0.3 watts or customers
who need 25 watts; all that's needed is a twist of the pot inside).

This circuit makes AM easy: just inject your audio in this control
circuit and with some luck you get reasonably-quality AM.
It won't be hi-fi but superreg receivers never notice;
similary there may be some FM but again superregs never notice
(and it's a nice way to be able to verify a transmitter w/o
the need to carry AM kit!)

Oh, since AM PEP power is 4 times the AM idle power, pls reduce
the idle output power to at most 25% of the max, or things will clip.

Ex-PMR equipment in many places is dime-a-dozen and this gives one
an easy way to build a transmitter for some RDF bootstrap activity,
or during a JOTA or thereabouts.

[I have one transmitter where I can fluently adjust the power from
50mW to 10W PEP, to adjust for the distance and the difficulty
of the RDF. This means that one can make a small hunt for the
young scouts and a larger hunt, with longer distances,
for the older folk, all with the same equipment.
Just a point for inspiration].

Hope this helps,

Geert Jan PE1HZG

> part is good layout/bypassing practices as someone pointed out.

I suppose I've been pursuing the path of open loop because that's what
most of the literature describes - mostly for reasons of efficiency I
suppose (as in the case of continuous broadcast/commercial AM) but -
now that you mention it - much of that doesn't apply here. The duty
cycle for transmissions is *really* low and short duration, and the output
levels are fairly modest (a few watts or so) - so the difference between
using some high-level modulation (e.g. transformer) on a Class C
final or doing series modulation through linear stages isn't really all
that significant. Guess I'll go re-think it... It makes sense to, as you
suggest, close the loop and govern the modulation where the "rubber
hits the road" (or airwaves).

The high-level mod scheme counts on doing a good job of
compression and limiting at the source - and then setting the final PA
to fall within a certain range. I assume that the closed-loop scheme
you suggest involves some "tastefully designed" VCAs somewhere
in that loop???

Thanks for the input! Lots to think about........

Tim,

You are really close to your own answer. I built a Faraday cage area
around my laptop. And also plugged into a surge/noise filter for
the AC and use metal hood cables to hook up to the radios.
I hardly experience any noise at all.

The reason is most manufacturer are turning to plastics and putting
less and less shielding in them. Keep in mind the OEM's are building
for the general public.

High power VHF/UHF AM transmitters are also used as audio subcarrier
transmitters in System-L television, which is used at least in France.
These require "full" audio bandwidth and good linearity for low audio
distortion in normal TV receivers. The audio exciters used in low
power relays might be in your power range, so try to find some info
about these transmitters, most likely only in French.

Hi and thanks for reading this,
has anyone out there got a copy of the building instructions for the white rose multiband receiver project?
This was featured in radcom (and i think Practical Wireless too) around early to mid 90's.
I have found a 1/2 bulit kit and band boards that I started years ago but true to form I have lost the article.
I was going to try to finish it as I have all the bits in bags (think they came from badger boards).
If anyone can help please let me know either here or via my email address bobstevensonREMOVETHIS@hotmail.com

You can get back issues of SPRAT where I recall it was also published
but I think that requires membership in the G-QRP Club.
The receiver is also featured in the "Low Power Scrapbook" if you're
willing to pony up US$20 for what seems to be a very good book.

Date: 2005-05-17 18:50:17 UTC
From: rrah@pencoys.org.uk
Message-ID: <428a3963.292526124@news.madasafish.com>
Source record: 18895

Hi folks, help needed I'm afraid.

I appear to have a problem with my FT980's PLL. I'm hoping its a stock fault and someone can point to the fault, but knowing my luck...

Its hard to describe what its doing, but it seems to be either going out of lock every 1Khz or so, or its getting something in the loop div/N wrong in some way. It currently appears to be heat sensitive and intermittant but I hope to get further and more useful description of the symptoms later. As far as I can tell, the CPU is functioning correctly and is driving the display etc ok.

Anyone care to describe how the thing works in simple terms? or know of a fairly straightforward test to determine the source of the problem.
I have the users manual and the technical manual from http:\\www.mods.dk in PDF form but nothing there seems to be all that useful at present.
I hope someone can help, all the best, Mike W

These are useful pointers.
I am in the same situation as the original poster.
I have been given a bunch of RF power transistors (316-01 and 244-04 type packages). I have been unable to identify them. The giver tried to find the information where he works (they were being thrown away) but he can't find any information.

Transistor 1 markings: C / M2519 / 185 / 9014 / RR15
the bag is labelled RF 10W UHF

Transistor 2 markings: C / 185 / 4340P3 / 8817 / MALAYSIA
the bag is labelled RF 12W VHF

Transistor 3 markings: C / (Motorola Wing) / 8133P1 / 8919 / MALAYSIA
the bag is labelled RF PA 28W VHF

Transistor 4 markings: C / 4340P1 / 8824 M52 / (logo)
the bag is labelled RF 4W VHF
these have logos of ST or Thompson CSF

The second from last line four digit number is the date code. In some cases there are more than one transistor and this line does vary.

I Have tried adding MRF, 2SC, SRF in front of the ID and then I have done a google, but this has found nothing.

Any ideas?

--Gary

Gary -

Transworld amplifiers used TRW transistors, but I believe those transistors started with a "9". Some of the former RF designers from that time can be found at QRZ.COM (Question and Answer forum).

2566. Pointers for a homebrew 2-meter XCVR

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-05-18 01:31:39 UTC
From: Bernard <bernard.debbasch_removethis_@mail.com>
Message-ID: <5Wwie.9489$jj.5508@lakeread06>
Source record: 18799

I have looked at homebrewing an FM 2-meter XCVR and already got help from this group. The goal is to spend time on something that others could duplicate and not work on a one of a kind.

First, why homebrewing ? Two reasons:

1) It is homebrewed
2) There is room for a "powerful" microprocessor that will do other things (APRS is one of them)

It seems that the problem is the selection of components that can be sourced in relatively low volume and at a reasonable cost by amateurs (read: Digikey, Mouser and alike).

Here is what I have found some far:

1) Transistors for RX front end: relatively easy to find if based on dual-gate MOSFET
2) RX band filters: I have decided to have a fixed capacitor and adjust the inductor.The availability of adjustable coils (Toko for example) has decreased in the last few years. Digikey only stocks a few of them but that should be OK in the near term.
3) First IF filters: not much choice since 10.7MHz and 21.4 MHz seem to be the only 2 frequencies stocked (most commercial boxes use between 35 and 70 MHz). The IF inductors/transformers at 10.7 MHz and 455 KHz have disappeared from Digikey (used to be there a few years ago).
4) 2nd IF + FM demodulator. The Motorola parts (MC33xx) are gone. The part that is found in many commercial XCVR is the Toshiba TA31136. This part is not stocked by Toshiba's distributors in the US (12 weeks lead time if you want to order 2K of them). Good news is that the Rohm BA4116FV is a pin-to-pin compatible device and it is available at Digikey for $1.26. I don't know if this part works since I have not seen it used anywhere...
5) 2nd mixer crystal. The 10.245 MHz crystals are easily available but not the 21.4 +/- .455. This seems to remove the option of using a 21.4 MHz IF..
6) 2nd IF filter. The 455 KHz ceramic filters seem to have a very limited availability. The exact type recommended by the IC vendor is hard to find..
7) FM discriminator. I could not find a source for the ceramic discriminator recommended by Toshiba/Rohm (CDLBLA455KCAY24-B0 which is the new P/N for the CDB450C24). I can understand the pain of the distributors since every FM IC requires a different discriminator. The discriminator coil that can be used instead is not easier to locate.
8) PLL: I am currently leaning towards National (LMX2306 or similar). They are cheap and available. NS has a nice PLL design tool online but the tool tries to convince me to switch to a better a part that I won't be able to handle (leadless package). It is clear that the new generations IC's are not designed for hand soldering at home...

9) Microprocessor and display: no problem here , plenty of choice.
10) TX chain transistors and PA Module: no problem with the regular vendors. www.rfparts.com seems to have a large selection of modules.
11) TX low pass filter: will need to be hand made. That's OK but who is selling tinned wire ?

Some notes:

1) I recently bought a dual conversion 72MHz RC receiver. For $45 (and 13 grams !), one can get one Toshiba TA31136FN, a ceramic discriminator, a 11.155 MHz (10.7 + .455) crystal, one 10.7 MHz crystal and one 455 kHz ceramic filters, one IF transformer, 3 adjustable inductors, one dual-gate mosfet (unidentified), a 3.3V regulator and more. I am not sure what to think except that this might be a non traditional way to source 1/2 of the RX section !
2) Some hard to find parts are sometime available as spare for Ham or commercial radios but the prices are generally too high to be considered.
3) One way to go around the hard to find parts is to go with a more discrete solution (no IF/Mixer/DEMOD/SQUELCH IC) and hand wire all the inductors. This is not the way I am planning to go.
4) English is my 2nd language. Excuse the grammar mistakes and hard to understand sentences.

But amateur radio has always been about scrounging. Once you know enough, you can make do in a lot of cases with what's available rather than what's specified. Indeed, over the decades many an article has been based on what the author had at hand (or in some cases what he thought would be readily available) rather than because there was something special about the parts. A beginner suffers from not knowing enough, and going down to the parts store with the list of parts and having no choice but to live with the prices, or if the parts aren't available. But once they have a more extensive understanding, they know that they can pull those bypass capacitors off that VCR, and use those generic transistors instead of the generic transistors specified in the article.

$45 is kind of expensive. Take any older cordless phone, and one is bound to find a double conversion (10.7MHz and 455KHz) FM receiver, often using one of those Motorola ICs. You can get them cheap at garage sales over here, I've stopped bothering with them because they are still plentiful (though I suppose a later generation will be less useful, being more compact and maybe using different IF frequencies). Indeed, buy the handset and the base unit, and you get two IF strips. The ones I've taken apart have a ceramic 10.7MHz filter, of the type you'd find in an FM broadcast receiver, but that happens in a lot of stuff. (Note there are some exceptions, where the units are single converstion dropping from 49MHz to 455KHz, but the one I picked up like that did still use one of those Motorola ICs.)

Before FRS took off, there were license free 49MHz superhet walkie talkies, that had dual conversion receivers with the better ones, and they could be adapted with a change of front end coils. These have faded away, so I don't know how available they are (I once bought a pair for twenty dollars at a garage sale), but they're is nothing forbidding their use.

Baby monitors maybe, but I've never taken one apart and because of their use I have my suspcions that they may be single conversion, and perhaps even superregen.

Old cellphones, the bigger and clunkier the better, offer up narrow band FM IF filters, and even complete IF strips. The first IF will usually be in the 45MHz or higher range, but given that they do include the conversion crystal to 455KHz, it doesn't really matter. The older ones are cheap now, and the further back you go the more discrete components you'll see. They'll be through-hole ICs, and identifiable, rather than more recent ones that are surface mount and much higher density where you can only use the ICs for the intended purpose.

One problem that has arisen is that construction articles in recent decades have become more about providing a kit to the builder. Expect the builder to copy it perfectly, buy the exact parts, and maybe even buy it as a kit from the author or a third party. Once that happens, the author focuses on using parts that are easy to come by, and the article is about "building it like this" instead of explaining the philosophy and possible alternatives to the parts. But it's only through understanding that people can look at a schematic and realize they can use that filter they have. The more they are spoon fed the more dependent they become.

I agree with Michael. A Radio/TV repair shop where they dispose of old
circuit boards or equipment that cost more $$ to repair ... gold mine of
parts (some discontinued -- just start desoldering)

DSP-10 designed by Bob Larkin, W7PUA. Kits on sale at Dayton and through
TAPR. For more information see http://www.proaxis.com/~boblark/dsp10.htm

Bernard, Michael: Thanks for this wonderful question and great answer.
Yea, scrounging and making do with what is available is the way to go.
There's a great book "First Light" by Richard Preston. It is about the
Palomar Mountain telescope. There is a section on the technical team
that builds the modern instruments used with the old 'scope. They got a
lot of their best parts by "dumpster diving" in California.

Last time I looked Digi-Key had a good selection of NEC parts.

The world seems to be going to direct-conversion I-Q receivers with the baseband going to a DSP for processing. Reverse for TX. I think this would work fine for any mode on 2m, including FM if you're clever with your algorithms.

Your written English is most definitely up to par -- if you hadn't
mentioned it I wouldn't be able to tell that you're not a native speaker.

Michael,

I did not intend to turn this thread into a philosophical debate (I had enough with the "no progress in decades" thread" !) but your are bringing a good point.

I should have stated more clearly that my intend is what you describe as "providing a kit to the builder". We may debate (please don't !) on the value that this brings to the builder. On a 1 to 10 scale, buying a transceiver is a 0 and building it from raw silicon, carbon and copper is a 10+. Where does building a "kit" from an article stand on that scale ? I guess somewhere between 1 and 9. But I am going to firmly defend the fact that it is more than zero. I can find many projects that anybody can build with spares (like many "one transistor radio") but I also believe that to go beyond that you need a PCB and an orderable parts list... When this is done, some may chose a path that will teach them a lot. More than 25 years ago, I did many mods on the first 2-meter FM transceiver that I owned. It was fun but finding the spare Japanese IC's that I burned in the process was a nightmare ! I whish I had done these mods on a XCVR that I built, even if I had to buy the PCB and the key components.

Good point on the 49 MHz intercom. I have a pair of them. And you are right, they have a wideband ceramic filter at 10.7 MHz. I guess they need to because they share the second conversion Xtal with the PLL (10.240 MHz) so the IF is really at 10.695 MHz (2nd if is at 455 KHz). This is confirmed by looking at the PLL datasheet. The bad news is that the PLL has a 60 MHz max input with preprogrammed channels. By the way, my intercom is not full-duplex but the phones are. May be somewhere someone is running a repeater with modified 49 MHz phone !

Thanks again !
Bernard

You are right, for example most of the 802.11 or Bluetooth solutions are zero-IF, but I don't think that this is ideal for Ham Radio (the main issue is re-injection of the LO into the RX). A better option (for us) is the low IF option (like in the DSP10). The DSP10 has an IF at 19.665 MHz and one at 15 KHz. The concept is excellent but slightly overdesigned for what I want to achieve. The drawback (when compared to zero-IF) is that the low-IF receivers still requires dual conversion and IF filters to achieve any level of performance.

Bernard,

If your goal is to make a kit that uses simple, commonly available components and exploits a 'powerful microprocessor' for flexibility, then DSP is definitely the way to go. If properly done, it virtually eliminates the need for all of the old ham-favorite special function chips.

With respect to 're-injection of the LO into the RX', I'm not quite sure what you mean. There is the potential for LO leakage out of the antenna port because the LO is on the receive frequency, but this is pretty easily managed with careful electrical and electro-mechanical design.

Nice goals, but your target market will be kind of limited. Whatever you come up with is going to cost 2-4x commercial. I can't really see the point of APRS. A nice, compact, inexpensive APRS box would be nice, but a homebrew VHF rig isn't going to get there. Now, maybe a little box with a TNC and GPS built in that would plug into an HT might come close, but that's not what you are focusing on here.

> 2) RX band filters: I have decided to have a fixed capacitor and adjust

That does make for harder parts selection. Why that choice?

> 5) 2nd mixer crystal. The 10.245 MHz crystals are easily available but not

10.7 is a pretty low first IF. You might consider using a higher IF and winding the transformers on toroids.

> 8) PLL: I am currently leaning towards National (LMX2306 or similar).
They

Think about DDS. There are some really nice DDS choices from Analog Devices and TI. TI has some really nice, cheap synthesizers. DDS is way less of a pain than PLL. TI's 440 MHz part can easily work down to 2 meters. Yes, they are pretty much all TSSOP but that is manageable to hand solder on a PCB. Messy to prototype but then that will be a problem at VHF anyway.

..

Most of the DDS and PLL chips are available in TSSOP. You don't need a
toaster oven for that, your typical soldering iron works just fine. Now, if
you had to resort to a BGA that would be a different story.

I would encourage Bernard to consider mostly SMT parts. SMT resistors and
caps are a lot more convenient than leaded, and a lot smaller. Eliminates
any issues with lead inductance, too. Maybe a little more expensive,
though.

OK, but you can get better noise figure from a GaAs part.

Mouser stocks a VERY nice line of low cost VHF shielded inductors. Google "xicon" and "tunable coil" on the Mouser website.

> 3) First IF filters: not much choice since 10.7MHz and 21.4 MHz seem to be

Again, Mouser is your friend -- google "xicon" and "transformer". If I were doing it, I'd do a 70 MHz. first IF and then 10.7 MHz. second IF. Forget dropping down to 455 unless you have to.

Phillips makes (made??) a nice line of FM ICs. You might give them a try.

> 5) 2nd mixer crystal. The 10.245 MHz crystals are easily available but not

> find..

Why crystals? You are going to have a synthesizer for the front end anyway, why not use the synthesizer crystal as your timebase and synthesize the mixer oscillator? You said you wanted some stuff for the microprocessor to do anyway; controlling a synthesizer is one of them. Or, you could get a parallel input synthesizer and hardwire it to a fixed frequency.

> 7) FM discriminator. I could not find a source for the ceramic

> coil that can be used instead is not easier to locate.

A discriminator (or ratio detector) is nothing more than a couple of transformers coupled bottom to top. You can make a two-coil ratio detector as easy as buying one.

> 11) TX low pass filter: will need to be hand made. That's OK but who is
> selling tinned wire ?

Why would you need tinned wire? Plain old magnet wire is easy to come by.

I can probably provide a little more information: The designations 4340P3, 8133P1 and 4340P1 are most likely abbreviated internal type designations/stock no. used by General Electric (and by the Danish company Storno that was acquired by GE and later by Motorola). The full number might be something like e.g. 19J704340P1, almost all designations starting with 19J...

Unfortunately, I have no longer the xref lists between the 19J-numbers and the more common mfg. designations.

The memo that has "IMPEACH HIM" written all over it.

The top-level government memo marked "SECRET AND STRICTLY PERSONAL", dated eight months before Bush sent us into Iraq, following a closed meeting with the President, reads, "Military action was now seen as inevitable. Bush wanted to remove Saddam through military action justified by the conjunction of terrorism and WMD. But the intelligence and facts were being fixed around the policy."

Read that again: "The intelligence and facts were being fixed...."

For years, after each damning report on BBC TV, viewers inevitably ask me, "Isn't this grounds for impeachment?" -- vote rigging, a blind eye to terror and the bin Ladens before 9-11, and so on. Evil, stupidity and self-dealing are shameful but not impeachable. What's needed is a "high crime or misdemeanor."

And if this ain't it, nothing is.

The memo uncovered this week by the TIMES, goes on to describe an elaborate plan by George Bush and British Prime Minister Tony Blair to hoodwink the lanet into supporting an attack on Iraq knowing full well the evidence for war was a phony.

A conspiracy to commit serial fraud is, under federal law, racketeering. However, the Mob's schemes never cost so many lives. Here's more. "Bush had made up his mind to take military action. But the case was thin. Saddam was not threatening his neighbors, and his WMD capability was less than that of Libya, North Korea or Iran."

Really? But Mr. Bush told us, "Intelligence gathered by this and other governments leaves no doubt that the Iraq regime continues to possess and conceal some of the most lethal weapons ever devised."

A month ago, the Silberman-Robb Commission issued its report on WMD intelligence before the war, dismissing claims that Bush fixed the facts with this snooty, condescending conclusion written directly to the President, "After a thorough review, the Commission found no indication that the Intelligence Community distorted the evidence regarding Iraq's weapons." We now know the report was a bogus 618 pages of thick whitewash aimed to let Bush off the hook for his murderous mendacity. Read on: The invasion build-up was then set, says the memo, "beginning 30 days before the US Congressional elections." Mission accomplished. You should parse the entire memo -- reprinted below -- and see if you can make it through its three pages without losing your lunch. Now sharp readers may note they didn't see this memo, in fact, printed in the New York Times. It wasn't. Rather, it was splashed across the front pages of the

Times of LONDON on Monday.

It has effectively finished the last, sorry remnants of Tony Blair's political career. (While his Labor Party will most assuredly win the elections Thursday, Prime Minister Blair is expected, possibly within months, to be shoved overboard in favor of his Chancellor of the Exchequer, a political execution which requires only a vote of the Labour party's members in Parliament.)

But in the US, barely a word. The New York Times covers this hard evidence of Bush's fabrication of a casus belli as some "British" elections story. Apparently, our President's fraud isn't "news fit to print."

My colleagues in the UK press have skewered Blair, digging out more incriminating memos, challenging the official government factoids and fibs. But in the US press nada, bubkes, zilch. Bush fixed the facts and somehow that's a story for "over there."

The Republicans impeached Bill Clinton over his cigar and Monica's affections. And the US media could print nothing else. Now, we have the stone, cold evidence of bending intelligence to sell us on death by the thousands, and neither a Republican Congress nor what is laughably called US journalism thought it worth a second look.

My friend Daniel Ellsberg once said that what's good about the American people is that you have to lie to them. What's bad about Americans is that it's so easy to do.

[Here it is - the secret smoking gun memo
- discovered by the Times of London. - GP]

SECRET AND STRICTLY PERSONAL - UK EYES ONLY
DAVID MANNING

From: Matthew Rycroft

Date: 23 July 2002 S 195 /02

cc: Defence Secretary,Foreign Secretary, Attorney-General,
Sir Richard Wilson, John Scarlett, Francis Richards, CDS, C,
Jonathan Powell, Sally Morgan, Alastair Campbell

IRAQ: PRIME MINISTER'S MEETING, 23 JULY

Copy addressees and you met the Prime Minister on 23 July to discuss Iraq.

This record is extremely sensitive. No further copies should be made. It should be shown only to those with a genuine need to know its contents.

John Scarlett summarised the intelligence and latest JIC assessment. Saddam's regime was tough and based on extreme fear. The only way to overthrow it was likely to be by massive military action. Saddam was worried and expected an attack, probably by air and land, but he was not convinced that it would be immediate or overwhelming. His regime expected their neighbours to line up with the US. Saddam knew that regular army morale was poor. Real support for Saddam among the public was probably narrowly based.

C reported on his recent talks in Washington. There was a perceptible shift in attitude. Military action was now seen as inevitable. Bush wanted to remove Saddam, through military action, justified by the conjunction of terrorism and WMD. But the intelligence and facts were being fixed around the policy. The NSC had no patience with the UN route, and no enthusiasm for publishing material on the Iraqi regime's record. There was little discussion in Washington of the aftermath after military action.

CDS said that military planners would brief CENTCOM on 1-2 August, Rumsfeld on 3 August and Bush on 4 August.

The two broad US options were:

(a) Generated Start. A slow build-up of 250,000 US troops, a short (72 hour) air campaign, then a move up to Baghdad from the south. Lead time of 90 days (30 days preparation plus 60 days deployment to Kuwait).

(b) Running Start. Use forces already in theatre (3 x 6,000), continuous air campaign, initiated by an Iraqi casus belli. Total lead time of 60 days with the air campaign beginning even earlier. A hazardous option.

The US saw the UK (and Kuwait) as essential, with basing in Diego Garcia and Cyprus critical for either option. Turkey and other Gulf states were also important, but less vital. The three main options for UK involvement were:

(i) Basing in Diego Garcia and Cyprus, plus three SF squadrons.

(ii) As above, with maritime and air assets in addition.

(iii) As above, plus a land contribution of up to 40,000, perhaps with a discrete role in Northern Iraq entering from Turkey, tying down two Iraqi divisions.

The Defence Secretary said that the US had already begun "spikes of activity" to put pressure on the regime. No decisions had been taken, but he thought the most likely timing in US minds for military action to begin was January, with the timeline beginning 30 days before the US Congressional elections.

The Foreign Secretary said he would discuss this with Colin Powell this week. It seemed clear that Bush had made up his mind to take military action, even if the timing was not yet decided. But the case was thin. Saddam was not threatening his neighbours, and his WMD capability was less than that of Libya, North Korea or Iran. We should work up a plan

for an ultimatum to Saddam to allow back in the UN weapons inspectors. This would also help with the legal justification for the use of force.

The Attorney-General said that the desire for regime change was not a legal base for military action. There were three possible legal bases: self-defence, humanitarian intervention, or UNSC authorisation. The first and second could not be the base in this case. Relying on UNSCR 1205 of three years ago would be difficult. The situation might of course change.

The Prime Minister said that it would make a big difference politically and legally if Saddam refused to allow in the UN inspectors. Regime change and WMD were linked in the sense that it was the regime that was producing the WMD. There were different strategies for dealing with Libya and Iran. If the political context were right, people would support regime change. The two key issues were whether the military plan worked and whether we had the political strategy to give the military plan the space to work.

On the first, CDS said that we did not know yet if the US battleplan was workable. The military were continuing to ask lots of questions.

For instance, what were the consequences, if Saddam used WMD on day one, or if Baghdad did not collapse and urban warfighting began? You said that Saddam could also use his WMD on Kuwait. Or on Israel, added the Defence Secretary.

The Foreign Secretary thought the US would not go ahead with a military plan unless convinced that it was a winning strategy. On this, US and UK interests converged. But on the political strategy, there could be US/UK differences. Despite US resistance, we should explore discreetly the ultimatum. Saddam would continue to play hard-ball with the UN.

John Scarlett assessed that Saddam would allow the inspectors back in only when he thought the threat of military action was real.

The Defence Secretary said that if the Prime Minister wanted UK military involvement, he would need to decide this early. He cautioned that many in the US did not think it worth going down the ultimatum route. It would be important for the Prime Minister to set out the political context to Bush.

Conclusions:

(a) We should work on the assumption that the UK would take part in any military action. But we needed a fuller picture of US planning before we could take any firm decisions. CDS should tell the US military that we were considering a range of options.

(b) The Prime Minister would revert on the question of whether funds could be spent in preparation for this operation.

(c) CDS would send the Prime Minister full details of the proposed military campaign and possible UK contributions by the end of the week.

(d) The Foreign Secretary would send the Prime Minister the background on the UN inspectors, and discreetly work up the ultimatum to Saddam. He would also send the Prime Minister advice on the positions of countries in the region especially Turkey, and of the key EU member states.

(e) John Scarlett would send the Prime Minister a full intelligence update.

(f) We must not ignore the legal issues: the Attorney-General would consider legal advice with FCO/MOD legal advisers. (I have written separately to commissionthis follow-up work.)

Bush wanted to remove Saddam through military action justified by the conjunction of terrorism and WMD. But the intelligence and facts were being fixed around the policy."

Read that again: "The intelligence and facts were being fixed...."

For years, after each damning report on BBC TV, viewers inevitably ask me, "Isn't this grounds for impeachment?" -- vote rigging, a blind eye to terror and the bin Ladens before 9-11, and so on. Evil, stupidity and self-dealing are shameful but not impeachable. What's needed is a "high crime or misdemeanor."

And if this ain't it, nothing is.

The memo uncovered this week by the TIMES, goes on to describe an elaborate plan by George Bush and British Prime Minister Tony Blair to hoodwink the lanet into supporting an attack on Iraq knowing full well the evidence for war was a phony.

A conspiracy to commit serial fraud is, under federal law, racketeering. However, the Mob's schemes never cost so many lives. Here's more. "Bush had made up his mind to take military action. But the case was thin. Saddam was not threatening his neighbors, and his WMD capability was less than that of Libya, North Korea or Iran."

Really? But Mr. Bush told us, "Intelligence gathered by this and other governments leaves no doubt that the Iraq regime continues to possess and conceal some of the most lethal weapons ever devised."

A month ago, the Silberman-Robb Commission issued its report on WMD intelligence before the war, dismissing claims that Bush fixed the facts with this snooty, condescending conclusion written directly to the President, "After a thorough review, the Commission found no indication that the Intelligence Community distorted the evidence regarding Iraq's weapons." We now know the report was a bogus 618 pages of thick whitewash aimed to let Bush off the hook for his murderous mendacity. Read on: The invasion build-up was then set, says the memo, "beginning 30 days before the US Congressional elections." Mission accomplished. You should parse the entire memo -- reprinted below -- and see if you can make it through its three pages without losing your lunch. Now sharp readers may note they didn't see this memo, in fact, printed in the New York Times. It wasn't. Rather, it was splashed across the front pages of the

Times of LONDON on Monday.

It has effectively finished the last, sorry remnants of Tony Blair's political career. (While his Labor Party will most assuredly win the elections Thursday, Prime Minister Blair is expected, possibly within months, to be shoved overboard in favor of his Chancellor of the Exchequer, a political execution which requires only a vote of the Labour party's members in Parliament.)

But in the US, barely a word. The New York Times covers this hard evidence of Bush's fabrication of a casus belli as some "British" elections story. Apparently, our President's fraud isn't "news fit to print."

My colleagues in the UK press have skewered Blair, digging out more incriminating memos, challenging the official government factoids and fibs. But in the US press nada, bubkes, zilch. Bush fixed the facts and somehow that's a story for "over there."

The Republicans impeached Bill Clinton over his cigar and Monica's affections. And the US media could print nothing else. Now, we have the stone, cold evidence of bending intelligence to sell us on death by the thousands, and neither a Republican Congress nor what is laughably called US journalism thought it worth a second look.

My friend Daniel Ellsberg once said that what's good about the American people is that you have to lie to them. What's bad about Americans is that it's so easy to do.

- discovered by the Times of London. - GP]

SECRET AND STRICTLY PERSONAL - UK EYES ONLY
DAVID MANNING

From: Matthew Rycroft

Date: 23 July 2002 S 195 /02

cc: Defence Secretary,Foreign Secretary, Attorney-General,
Sir Richard Wilson, John Scarlett, Francis Richards, CDS, C,
Jonathan Powell, Sally Morgan, Alastair Campbell

IRAQ: PRIME MINISTER'S MEETING, 23 JULY

Copy addressees and you met the Prime Minister on 23 July to discuss Iraq.

This record is extremely sensitive. No further copies should be made. It should be shown only to those with a genuine need to know its contents.

John Scarlett summarised the intelligence and latest JIC assessment. Saddam's regime was tough and based on extreme fear. The only way to overthrow it was likely to be by massive military action. Saddam was worried and expected an attack, probably by air and land, but he was not convinced that it would be immediate or overwhelming. His regime expected their neighbours to line up with the US. Saddam knew that regular army morale was poor. Real support for Saddam among the public was probably narrowly based.

C reported on his recent talks in Washington. There was a perceptible shift in attitude. Military action was now seen as inevitable. Bush wanted to remove Saddam, through military action, justified by the conjunction of terrorism and WMD. But the intelligence and facts were being fixed around the policy. The NSC had no patience with the UN route, and no enthusiasm for publishing material on the Iraqi regime's record. There was little discussion in Washington of the aftermath after military action.

CDS said that military planners would brief CENTCOM on 1-2 August, Rumsfeld on 3 August and Bush on 4 August.

The two broad US options were:

(a) Generated Start. A slow build-up of 250,000 US troops, a short (72 hour) air campaign, then a move up to Baghdad from the south. Lead time of 90 days (30 days preparation plus 60 days deployment to Kuwait).

(b) Running Start. Use forces already in theatre (3 x 6,000), continuous air campaign, initiated by an Iraqi casus belli. Total lead time of 60 days with the air campaign beginning even earlier. A hazardous option.

The US saw the UK (and Kuwait) as essential, with basing in Diego Garcia and Cyprus critical for either option. Turkey and other Gulf states were also important, but less vital. The three main options for UK involvement were:

(i) Basing in Diego Garcia and Cyprus, plus three SF squadrons.

(ii) As above, with maritime and air assets in addition.

(iii) As above, plus a land contribution of up to 40,000, perhaps with a discrete role in Northern Iraq entering from Turkey, tying down two Iraqi divisions.

The Defence Secretary said that the US had already begun "spikes of activity" to put pressure on the regime. No decisions had been taken, but he thought the most likely timing in US minds for military action to begin was January, with the timeline beginning 30 days before the US Congressional elections.

The Foreign Secretary said he would discuss this with Colin Powell this week. It seemed clear that Bush had made up his mind to take military action, even if the timing was not yet decided. But the case was thin. Saddam was not threatening his neighbours, and his WMD capability was less than that of Libya, North Korea or Iran. We should work up a plan

for an ultimatum to Saddam to allow back in the UN weapons inspectors. This would also help with the legal justification for the use of force.

The Attorney-General said that the desire for regime change was not a legal base for military action. There were three possible legal bases: self-defence, humanitarian intervention, or UNSC authorisation. The first and second could not be the base in this case. Relying on UNSCR 1205 of three years ago would be difficult. The situation might of course change.

The Prime Minister said that it would make a big difference politically and legally if Saddam refused to allow in the UN inspectors. Regime change and WMD were linked in the sense that it was the regime that was producing the WMD. There were different strategies for dealing with Libya and Iran. If the political context were right, people would support regime change. The two key issues were whether the military plan worked and whether we had the political strategy to give the military plan the space to work.

On the first, CDS said that we did not know yet if the US battleplan was workable. The military were continuing to ask lots of questions.

For instance, what were the consequences, if Saddam used WMD on day one, or if Baghdad did not collapse and urban warfighting began? You said that Saddam could also use his WMD on Kuwait. Or on Israel, added the Defence Secretary.

The Foreign Secretary thought the US would not go ahead with a military plan unless convinced that it was a winning strategy. On this, US and UK interests converged. But on the political strategy, there could be US/UK differences. Despite US resistance, we should explore discreetly the ultimatum. Saddam would continue to play hard-ball with the UN.

John Scarlett assessed that Saddam would allow the inspectors back in only when he thought the threat of military action was real.

The Defence Secretary said that if the Prime Minister wanted UK military involvement, he would need to decide this early. He cautioned that many in the US did not think it worth going down the ultimatum route. It would be important for the Prime Minister to set out the political context to Bush.

Conclusions:

(a) We should work on the assumption that the UK would take part in any military action. But we needed a fuller picture of US planning before we could take any firm decisions. CDS should tell the US military that we were considering a range of options.

(b) The Prime Minister would revert on the question of whether funds could be spent in preparation for this operation.

(c) CDS would send the Prime Minister full details of the proposed military campaign and possible UK contributions by the end of the week.

(d) The Foreign Secretary would send the Prime Minister the background on the UN inspectors, and discreetly work up the ultimatum to Saddam. He would also send the Prime Minister advice on the positions of countries in the region especially Turkey, and of the key EU member states.

(e) John Scarlett would send the Prime Minister a full intelligence update.

(f) We must not ignore the legal issues: the Attorney-General would consider legal advice with FCO/MOD legal advisers. (I have written separately to commissionthis follow-up work.)

Thanks for all the comments. Here is some feedback:

The Palomar telescope: quite an interesting story. My answer: would it be better if many could build their own with parts from Sears and Home Depot or is it better as a one of a kind made from Southern California trash ?

DSP10: definitely a very good design but with a different goal. I think that adding a DSP substantially increases the barrier to entry but I take note that this was suggested a few times (even if it will end up just replacing a $1.26 demodulator). In the TX chain the DSP implementation is actually more complicated because it would require an additional mixer (assuming that the only goal is FM) instead of directly modulating the VCO.

Taking parts from Radio and TV: this is how I got started in electronic 30 years ago. I would not suggest it to someone who is starting in the hobby. One reason is Murphy. This TV might be in the dumpster just because the one part you need failed !

Dan's Small Parts (http://www.danssmallpartsandkits.net/): very good, thanks for the link. I would sometimes want more information about some parts but I guess this is why there is a phone number to call.

Toaster reflow: I will look into this but this getting border line for me ! I decided a few years a go to stop making my own PCB's and order them online (APC circuit or alike). I may do the same for soldering !

Market for APRS + XCVR: I am not looking at it in term of market but rather combining 2 interests (RF and ΦP) on one platform.

Zero-IF: I don't know if this has been done in a decent 2-meter receiver. If anyone has a pointer I would be interested

Experimental Methods in RF Design: it is on my list of book to buy now (if you own this book, check the errata. They are online).

Mouser: I will have a better look at their line of inductors (by the way, I prefer adjusting the inductor due to some old memories of melting adjustable capacitors !)

Philips: yes I looked at them. The only part they have left is the SA615. This market is more or less gone. The big professional users are moving to digital voice...

TI: they have fast D/A (400 MHZ) out of which a motivated hobbiest could build a DDS but I did not see synthesizers or DDS parts. I will double check and have a second look at ADI's DDS

I will update the group after I make up my mind...

Bernard

I can see this will be a difficult project for you....maybe not
technically, but emotionally.

If I may say so...

I find homebrewing 'any something' falls into one of two broad categories.

One is to play around with the mind of experimentation, not to spend
too much money at the outset, to learn from the failures, and have the
project on the shelf eternally awaiting modifications for better
performance.... and typically at several times the cost of a commercial
ready-made equivalent.

Two - would be trying actually build something state-of-the-art and
trouble-free with the anticipation of actually using it on a daily
basis....and typically at several times the cost of a commercial
ready-made equivalent :-)

Neither is bad but they are entirely different disciplines to the hobby
of rolling your own and this has to be determined early on as you plan
the project. Most of us wind up somewhere between the two extremes. "It
works great, but..." Over-thinking the project often results in never
getting started.

www.gateway2call.com PC-to-phone and broadband phone services enable you to make and receive worldwide calls with incredibly low rates. Anyone with a broadband (high-speed) internet access can use their PC, regular phone or cordless phone to make unlimited calls from anywhere to anywhere in the U.S. , Canada, & up to 36 countries for one low monthly rate. The Pay-as-you-go's call plans will meet users who prefer to go for the low per minute International toll rates when needs arise. Manage your account online, Our voicemail will auto forward voicemail to your email as an attachment when you are not available, forward call to any phone and more. Talk smart with clear connections for a fraction of the cost of regular long distance phone calls.

Tired of using headphones and a computer! Just pick up a normal touch-tone phone or cordless phone, dial a phone number and start talking! Our broadband phones use the latest technology to send your calls over the Internet to bring you the greatest features, save you money and still give you stable, reliable phone service! Our call servers support most Gateway systems and phone adaptors.

Gateway2call offers home and business plans to meet all your needs. Several plans include unlimited calling within the US and Canada. You may choose a monthly plan that comes with free Incoming phone number or a toll free 800 number so you are always get connected any time anywhere from any regular phone or mobile.

Please visit www.gateway2call.com for more exciting features and call plans, one will suit your personal or business needs.

Maybe use an image from a plain old AD9850 or AD9851... no need for a
fast clock if you only want to cover a 4 MHz chunk of spectrum.

The National and Analog PLL chips are great, but not needed here.

<jim@rstengineering.com> wrote:

>> 1) Transistors for RX front end: relatively easy to find if based on
>> dual-gate MOSFET
>
>OK, but you can get better noise figure from a GaAs part.

True, however most uses for 2m a good transistor or fet will be
adaquate and likely easier to use. GaAs fets are harder to use
and can easily take off at microwave and harder to find.

For real fast lashups I've used MAR or ERA (MiniCircuits) MIMICS
and they are the easiest way to get good stable and predictable
gain at VHF through microwave and a kit of 30pieces was
around 49$ (ERA 1,2, and 3types). Parts can be had for
under 2$US in singles. Compared to transistors, FETs and
GaAs devices they are noiser but for a lot of things a MAR6
at 3db and 20DB gain to 1000mhz is not shabby.

>> 2) RX band filters: I have decided to have a fixed capacitor and adjust
>> the inductor.The availability of adjustable coils (Toko for example) has
>> decreased in the last few years. Digikey only stocks a few of them but
>> that should be OK in the near term.
>
>Mouser stocks a VERY nice line of low cost VHF shielded inductors. Google
>"xicon" and "tunable coil" on the Mouser website.

There are many suppliers. For 2m use it's possible to design with a
bandpass frontend easily and then tuning is less an issue. I just
wind coils and bend them as needed to tune. Programs to calculate
a coild for that are easy to find on the 'net.

>> 3) First IF filters: not much choice since 10.7MHz and 21.4 MHz seem to be
>> the only 2 frequencies stocked (most commercial boxes use between 35 and
>> 70 MHz). The IF inductors/transformers at 10.7 MHz and 455 KHz have
>> disappeared from Digikey (used to be there a few years ago).

However for those who care to it's possibel to roll your own. Ladder
filters using very common 20 or 24 mhz clock crystals are do able.

>Again, Mouser is your friend -- google "xicon" and "transformer". If I were
>doing it, I'd do a 70 MHz. first IF and then 10.7 MHz. second IF. Forget
>dropping down to 455 unless you have to.

Dual conversion using Murata and other 455khz filters is easy.
Motorola (3357 and friends) and other have a complete dual conversion

IF (everthing after first mixer) in a DIP and all you need is 10.7,
CFU455 filters and 455 if can for the quadarture dectector and 10.245
mixer crystal. These are easily ripped from:

Baby monitors, (flea markets and garage sales)
49mhz hts (non supperregen) (flea markets and garage sales)
Old scanners (flea markets and garage sales)
Other older radios that have been 4d (4d diseased, dying, dead
or decaying). (flea markets and garage sales)

>> 4) 2nd IF + FM demodulator. The Motorola parts (MC33xx) are gone. The part
>> that is found in many commercial XCVR is the Toshiba TA31136. This part is
>> not stocked by Toshiba's distributors in the US (12 weeks lead time if you

>> pin-to-pin compatible device and it is available at Digikey for $1.26. I
>> don't know if this part works since I have not seen it used anywhere...

There are suppliers selling NOS motorola parts:

http://www.danssmallpartsandkits.net/ has them sometimes
http://partsandkits.com/parts.asp has the 3362 at 2 for 4$ (good
source for toroids, NE602 and other bits).

>Phillips makes (made??) a nice line of FM ICs. You might give them a try.

The 604 can be hard to find.

>> 6) 2nd IF filter. The 455 KHz ceramic filters seem to have a very limited
>> availability. The exact type recommended by the IC vendor is hard to
>> find..

Often thats easy to substitute and wider (15kc) ones are easy to find.

>Why crystals? You are going to have a synthesizer for the front end anyway,
>why not use the synthesizer crystal as your timebase and synthesize the
>mixer oscillator? You said you wanted some stuff for the microprocessor to
>do anyway; controlling a synthesizer is one of them. Or, you could get a
>parallel input synthesizer and hardwire it to a fixed frequency.

The only way to go unless you doing a repeater or other fixed
frequency application. One caveat, it's far easier to create a clean
crystal LO chain and for super low noise frontends the LO must also
have narrow noise sidebands.

>> 7) FM discriminator. I could not find a source for the ceramic
>> discriminator recommended by Toshiba/Rohm (CDLBLA455KCAY24-B0 which is the
>> new P/N for the CDB450C24). I can understand the pain of the distributors

>> coil that can be used instead is not easier to locate.
>
>A discriminator (or ratio detector) is nothing more than a couple of
>transformers coupled bottom to top. You can make a two-coil ratio detector
>as easy as buying one.

True, the ratshlock PRO4, Pro12, series and the Pro7 series scanners used a trnsistor 455khs IF and two common IF cans for a discriminator with excellent results. The transistors were of the 2n2222/2n3904 equivelent class easily gotten form JDR at 4-6 cents each.

You can do a quadrature detector using a single IF can and a NE602 mixer.

>> 11) TX low pass filter: will need to be hand made. That's OK but who is
>> selling tinned wire ?
>
>Why would you need tinned wire? Plain old magnet wire is easy to come by.

Yep! tinned is not a requirement. Besides of you do it right you not going to need much.

I've used MAR6 mimic (cheap from Minicircuits) as RF with a TUF1 DBM feeding a MPF102 fet with it's output running into a textbook 3357 if chain for both 2m and similar for 440 and it's clean, easy and plenty of gain (sub .12 uv for 10db quieting FM). The Moto 3357 came from a 49mhz HT along with the 10.245 crystal, 10.7 filters and 455filter. I used a moto 145170 pll for the LO. Since the 3367 also does metering and squelch all it needed was audio (LM386-N). The front end was low loss (1db) bandpass before the MAR6 and image stripping (Higher loss bandpass) after the MAR6. the DBM can be one of a dozen different parts had cheap or even hand made (1n914s work ok at 2m). The post DBM fet was not optimized for gain only to buffer the DBM from the Crytal filter (10.7mhz).

Of course of you want something as a kit Ramsy has a FM rx for (FR146C is 2m, they have 10m, 6m and 220) that can be used for that range and has fair rx performance but needs either crystal control (NE602 VFO is not adaquately stable) or PLL either of which is usable with that. (it's cheap too! 44.95$US). They do about .7 uV for decent quieting and they do also sell a RF preamp thats decent. I've built both and they work as expected using the VFO and better with crystal control.

For experimentors its possible to do it. Parts even old ones are often found from small suppliers at resonable prices. Like someone said earlier learning where and what to look for is a big part of home made radio systems. It also helps to learn how to strip and use "old" parts.

Then there are people like me. I build in the middle. I often want
something that may not be state of the art (but still works excellent)
and is specifically not feature laden yet still require stable and
robust operation. I've done 6m transceivers that easily hear better
than the best and TX with a clean high quality signal that are not
state of the art. Please never equate the lack of state of the art
with well executed design as the latter can be as good or better due
to fewer compromizes that a production design might suffer. Shielding
is one matter where the homebrewer can easily exceed commerial.

Another area is designs where labor counts. Often my time is cheap
but using a commercial coil or crystal filter is not. So making my
own may factor $s for time.

>Neither is bad but they are entirely different disciplines to the hobby

>works great, but..." Over-thinking the project often results in never
>getting started.
>

>-Bill

That kills most projects! Sometimes it's "better" to plunge in and
have a few bits that fail or just done meet expectations. If the
midset is right you just redesign it, replace it and keep building.
Sometimes along the way you can also make a discovery
that will enlighten.

I have an aero. search and rescue beacon transceiver from a Govt.
surplus store.
When I connect the homemade(bike spoke) ant. to the casing(at the same

time it is connected to the proper ant.input site) it changes to
receiving a different air to ground conversation,than if I don't
connect it to the casing.I presume it must be changing the frequency of

transmission received.
Why/how does this occur?.
Thanks.

All the cases I have bought have a metal insert that mounts behind the
plastic front piece. If that isn't there a simple piece of aluminum screen
wire could be cut and fit on the back side of the drive bay.

Tim..

Having dabbled around in this noisy rf environment for
about 20 years..the following things will help:

1. The Antec Sonata is a good starting point as far
as cases go.
2. Get away from the noise of the convential CRT
monitor! Check on a good Flat panel from NEC or
Samsung and many others. Study up on the FCC type
shielding they adhere to...usually Canada, Japan
Korea and others. Usually they are represented by the
series of stickers of authenication as to rf rules
they adhere to. This has improved over time.

Also, some old video cards have a lot of rf type noise.
If you have an older sound card, many of them have
digital/analogue converters that sing with noise and
Rf.

Be extremely awsare of any "switching power supplies"
these are a nightmare, generally, in a radio environment.
Stay away from these supplies..confirm that it is not
a switching supply.

Also, the battery back up power supply has
the same problem in a radio environment...they
emit unbearable noise on most radios..particularly
on the 80/75 meter bands.

Put your PCI card slot metal shields in where
you've removed the PCI card. Also, most of the
good cases, including the Antec, have some RF
shields..I've never proven to myself if these
work or not..however, these in theory help
maintain a lot of RF energy from escaping from the
above mentioned components..however, it is best
to get a better built component that does not
radiate much RF.

Make sure the radio is removed from the PC area as
far as possible...also note the reduction in noise
at different angles from the PC. Mind you, an old
CRT monitor will wipe you out with noise. A small
palm held am radio put next to a pc will help

find out which component is offending you. Note
also, on difficult situations, there are all types
of shielding material. Don't overlook your AC power
and noise brought in on the lines. Some power
filtering supplies from some cable suppliers
will help.

Good luck,

Leonard...

P.S some cheap fans cause electrical noise.
Again pc positioning is critical.
Google on rf shielding material

All PC power supplies are of the switching type.

A laptop running on it's batteries may be the quietest out-of-the-box
system.

A "KVM" (remote "keyboard/video/mouse") box will allow you to put your
PC many feet away from your radio. Use this with an LCD screen.

Some models are here: http://makeashorterlink.com/?E27C22D1B

What would that help, unless we are talking about at least one hundred
meters ?

The important thing is to keep the radiation away from the _antenna_.

For the direct connection of noise from the computer to the radio,
audio transformers can be used to connect the sound card to the radio
and an optoisolator for the PTT signal. This will eliminate any direct
galvanic connection between the systems, thus preventing noise
currents from flowing from the computer via the radio to the antenna
ground, causing all kinds of interference on the way.

As I said above, it is important to minimise the radiation from the
computer from reaching the antenna.

Professional receivers like the ones from Watkins -Johnson have internal
(obviously high quality) SMPS

> Also, the battery back up power supply has

I have an APC - Back-UPS PRO650 less than a metre away from my TenTec
transceiver and do NOT suffer from noise on any band ,because of this UPS
(which is always on -line).

****
i use 2 of the APC CS 500. lot of noise. i wraped both in alu-screening.
and grounded both to third pin on the mains. cleared up that noise. and,
if you use a router, check out the d-link- DI604. i used a link-sys for
too many years. they were cheap and easy to set up. tried all the known
name routers. ended up with the d-link DI-604. no noise at all. i have
a friend who's a manager for compUSA, and she let me try a bunch. this
is
wired, i didn't try the wireless units...
good luck/ just my 2 cents...

Hi,

If it is a UK SARBE unit made by Burndept, it probably uses a super-regenrative receiver (i.e. self-oscillating detector) hence the tendency to pull in frequency. They were designed as a 'downed-airman' distress beacon on 121.5 or 243MHz (usually with a secondary non-distress channel), where the receive specification doesn't need to be particularly high and with a low battery consumption figure.

Horrible things, although I guess they will have saved a good few lives in their time.

Cheers - Joe

And all I got out of Chip and his $200,000,000 lawsuit threat was a friggin threatening e-mail instead of a hard copy with seals and stamps. You guys are tops!

Wonder how much I could sell the email copy for?

This line alone is priceless.

"Sir: I am not "Snake Oil...". This statement and others are highly injurious and being made upon a public forum which has many readers who are involved in buying decisions, indeed, at the present time and near to long term. I have grave concerns that the continued injury of your statement will affect sales on this line of antennas, which has an immediate market niche in excess of $200 million in sales."

And for legal purposes, I hereby disclaim any knowledge of this person's sanity or how this found its way to my email box.

And to save the bother...I hereby retract all of this posting so as to not continue any injury.

I'll start the bidding at -0.01 and put on a reserve that I will not pay more than One US Dime to supply the entire text to the lucky high-bidder.

-Bill

As do the expensive ones as well. The $30 - $40 ones I've used had
metal pieces that had to be removed from the 5 1/4" bays to use them.
Unfortunately when in use the drives have plastic fronts even if they
do have a metal chassis.

>
>Most of the fancier cases in the computer stores around here have

Standard is metal, fancy is a plastic insert with metal cross pieces
and a lighted fan for effects.
Surprisingly, those come with metal covers over the drive bays behind
the plastic ones in the front panel.
>
>Rack-mount server cases seem to be pretty good in terms of metal
>shielding all around but I need something for desktop use.
>
>Any suggestions? If all else fails I can just put some perforated

Find a local computer store and look at the cases they handle. Look
them over and find which ones have the metal pieces over the drive
bays. They aren't inserts, they are actually part of the front
stamping and have to be broken out. Sorta like knockouts in
electrical boxes.

However, I doubt you will find much relief even with a full metal
case.

I built up all 4 computers we use here using standard parts.

Now, I have one of those with the plastic insert on the side setting about a foot and a half below my rigs (Icom 756 Pro, Alpha 76A, Alinco DR610T, and Kenwood TMV7A. The computer is an MSI K7N2Delta Platinum with a 3.2 Gig Athlon, 1 Gig 400 MHz CAS-2 DDR Ram, 400 Gig SATA RAID, and three EIDE 7200 RPM HDs totaling 920 Gig. The monitor (19" CRT)sets directly above the two duobanders. About three feet to the left is this computer which is the standard all metal case with an MSI K8N Neo Series with a 3.4 Gig 64-bit Athlon, 2 Gig 400 MHz Dual, DDR RAM.and about 650 Gig of HD space. (I don't have the SATA RAID installed yet.) The monitor is a 17" NEC 1760v. Each computer is on its own UPS.

All have the dual layer, high speed DVD R/W drives and are part of a gigabit network that has two more computers. There is a 5 port gigabit switch, router, and cable modem less than two feet to the left of the duobanders and just over three feet from the HF rig. (I also run the legal limit from 160 through 10)

I have no detectable interaction between the rigs and the computer system in the house. The one in the shop will break the squelch if you put the HT next to the case, or hold the antenna for the best pick up, out to about 3')

I just brought the HT (VX-7R) in and the squelch did not open even when touching the antenna to the individual computer cases.
I should add that right now the network is running near capacity with backups across the network and several large downloads from the cable modem.

My wife's computer is about 15 feet to the south (in another room) and I do not hear it with the HT in there. The one is the shop is at the end of about 115 feet of Cat-5e and I use the HT within a foot of the monitor. That one is only a 2 Gig Athlon, but it too has 620Gig of HD space and a 19" CRT monitor. Those too are MSI motherboards with my wife's being a K7N2 Delta series and 2.8 Gig Athlon. I've forgotten the model of the one in the shop, but it's the oldest of the four. BTW, that case is also one of those with the plastic side windows and lighted fan.<:-))

Whether it's the motherboards, the cases, grounding, or a combination, I don't know, but interference has not been a problem...unless you count the electric fence across the road. Why I can not pick up the computers at all in here, but can open the squelch out to about 3' from the computer in the shop under ideal conditions I have no idea. I think it's more of a crap shoot. Some high end systems bother as bad as some low end systems while some low end systems cause no problems.

All four computers run 24 X 7.

I have an entire collection of E-mails. When I had my other website up, one of the links went to the Liberty Net. He concluded from this that he also had a case against me for anti Semitism. He was supposed to serve me in three days, I had a countdown clock on the website counting the days. When it finally got up to 167 days I took it off.

If you really want a letter of your very own, go to QRZ and offer fractal Antenna kits for sale. :>)

If you have an eBay account, you can add it to your watch list and see
the results.

I would like to know more about this as my curiosity has been tweaked.
I did a search and find mostly works from the person but no
interaction that would cause such a letter.

Where might I learn more?

>
>Roy Lewallen, W7EL

I don't know about the 'caustic comment', but I believe the OP has a
serious lack of understanding about both manufacturing and marketing.
The radios we use today are extremely complex and sophisticated.
Keeping everything from interacting and interfering with each other
inside seems to be a challenge for engineers. How much more a
challenge would a radio as he suggested be? Also, from a marketing
stand point, has he noticed how Kenwood and Icom connections are so
very different? The manufacturers don't want users using many outside
options. And what about the cost of adding all those connections for
the competitors to add modules? Who gets to pay for all that? If you
do get one, how do you know it won't draw too much current and burn up
something else, interact with another component causing RFI, or
what-have-you?

If there should be progress, it should be in the software operation of
these rigs. I believe there is much progress there, although in
regards to the 706 line, Icom does have some room for improvement.

just my opinion...

Source record: 18751

Can someone help me? I'd like to come up with a freq doubler that will do 1 GHz to 2 GHz (from a 500MHz to 1Ghz source). I thought of using a mixer and simply tieing the RF and LO and getting my out on the IF, but all the spec's for all the parts I've seen are assuming downconversion, and the RF & IF is in the multi-GHz ranges, while the IF is below 1.5 GHz at best. I also seem to remember reading somewhere, that you can also use the IF port as the RF port, and get the result from the (original) RF port. Will this work? I'm working with about a 1-5 dbm signal (I guess I can through in an mmic if I need more power, but I'd like to keep the circuit small).
I haven't quite been down the road of tripling yet, as I'd like to keep the error multiplication down (2 is better than 3).

http://www.minicircuits.com/dg03-204.pdf

Here's their line of doublers. All involve 12-15dB of conversion loss,
and want input signals on the order of 10-15 dBm input levels, so
you're going to have to boost the signal before the multiplier as well
as after (as well as doing some filtering to remove unwanted f1, f3,
and f4 products).

The AK-3000 and RK-3000 doublers are thru-hole packages with 70-1500
MHz in, 140-3000 MHz out. They want 12-15dBm input power, and have a
10-16dB conversion loss depending on frequency, phase of the moon, and
other characteristics. They run $60.

The MK-5 is 10-1000 in, 20-2000 out with 10-20 dBm input power and
13-17 dB conversion loss. It's in a fancy little box with SMA input
and output, yours for only $77.

You can find a lot of mini-circuits stuff on eBay, but I don't see the
doublers there very often.

Just go back in time on this conference a few years back. He used to send out his nastygrams to anyone who derided his fractal antenna.

He saw more enemies than Nixon!

In a single day it was not unusual to see 10 threats of lawsuits against various denizens of this conference.

As is my perverse nature, I reveled in tweaking him. I have several of the type on E-Bay as well as from his "attorney" telling me to cease and desist the manufacture of fractal antennas.

Thanks alot for the explaination,Joe.
Yes, it is made by Burndept Co.,'S.A.R.Be.,with voice'.
Therefore its a transceiver,with distress bleeper.
When its on receive without earthing the ant. to the body it
interferes with BBC1 reception.
It was yellow, but has been poorly painted in camo. colours, prob. by
Army.
It has what looks like a small lead acid battery connected, but I cant
get it to charge or work. I use a 9v d.c. supply to work it.
Thanks, Hartly.

Hartly,

> It has what looks like a small lead acid battery connected, but I cant
> get it to charge or work. I use a 9v d.c. supply to work it.
> Thanks, Hartly.

Years ago, one of the departments under me used to repair SABRE's.
There is an official battery adaptor but they used to take the guts out
of an unserviceable battery, drill a hole in the fluted end and feed
wires into it. I cannot remember the battery type as it was some years
ago but I don't think that it was ordinary carbon zinc, alkaline or even
NiCad/NiMH.

The idea as I remember it was for there to be a beacon (alternating
tones) on the distress channel and an airman to rescue craft talk-back
channel for when they got close to him/her. We used them on different
frequencies though for ground to helicopter liaison which was not very
mission critical. You could easily heave it and try another one if need
be. I once pulled the ring on one of the older models when in a mate's
car and it nearly put his eye out when the antenna suddenly unfurled :-(

Cheers - Joe

Those are called "small pattern nuts" and are readily available at a good hardware store. Available among many at "Bolts and nuts" in Asheville, NC. Will sell you 1 or 100 .

A good source to know about is McMaster-Carr at www.mcmaster.com

They have an amazing variety of fasteners and materials and tools.

Not the cheapest always, but no minimum order and next day delivery to
most places in the US.

Happy trails,
Gary (net.yogi.bear)

I thought that by putting 10 to 20 standard nuts side by side tight on a screw ,you could quickly grind the lot to size. Especially with brass, filing to size ,by clamping in a vice, would be a snip.

Thanks for the suggestions.
The "small pattern" helped, but have to question the "readily available"
part.
I called all the main hardwares in my area and no luck.
Did find in McMaster, but steel not brass. Guess they will have to do, and
match the plated solder lugs anyway.
Thanks again.

Look for contractor supplies and the like. Even out here in the boonies we
have an outlet that specializes in fasteners. Their store is a huge
warehouse with nothing but nuts and bolts. Not a regular hardware but a
place the caters to contractors.

If nothing local try www.almabolt.com

Can you make (or buy) a broadband transformer with a center-tapped secondary, and use a pair of Schottky diodes arranged just like a full-wave rectifier? At your low power level, I suppose you'll want at least a 1:1:1 transformer ratio, and 1:2:2 likely will be better. Some experiments or careful Spice simulations with good models should help optimize the conversion efficiency, which won't be wonderful at those low levels because of the drop in the diodes. Be sure to provide a DC return path for the diodes or it's not going to work.

Since that balanced push-push circuit suppresses the fundamental and third harmonics, you can get _nearly_ an octave of coverage with a single set of good filters, but note that 2*500MHz = 1000MHz, and 4*500MHz will also be generated, yielding 2000MHz output at the same time, which would be passed by your filter. Will that be a problem to you?

Cheers,
Tom

2638. AGC Design?

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-05-25 03:08:51 UTC
From: Tom Holden <holden_family@sympatico.ca>
Message-ID: <8%Rke.6363$dZ5.579272@news20.bellglobal.com>
Source record: 18771
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.shortwave

I'm looking for some advice/guidance on the design of AGC detection and timing circuits, prompted by some level of frustration with a modification I have been doing to a DX-394 SW radio. My questions, though, probably apply to receiver design generally. I have a problem with stability - the receiver gain oscillates at medium and fast release speeds.

Previously I had done a mod that pretty successfully provided 3 release speeds for the DX-394 but fell short of what I thought was the ideal: an attack time of ~1 millisecond, independent of the release time. That was based on a survey of receivers from which I concluded that the attack should be less than 13 ms and that 1 ms seemed to be the goal. Release speeds should probably be on the order of 30ms, 300ms and 3 seconds, for fast, medium and slow, respectively, although there seems to be lots of scope for subjective preference. My mod required a rather large capacitor for Slow release so my Slow was more like 1.2 seconds and the attack was slowed to maybe 50-70 ms for the slow release..

The objectives of the enhanced mod are to:
a) improve the attack speed to better less than 13ms for all release speeds
b) extend the Slow release using smaller cap
c) reduce the loading of the AGC detector on the output of the 2nd IF amp and also possible distortion due to the AGC and AM/Product detectors fed in parallel

I used a JFET to buffer between the IF amp and the diode detector and an emitter follower between the attack R-C circuit and the release R-C circuit, dc coupled to the stock AGC amplifier. On the release side, about 1/10 the capacitance vs the earlier mod is required for slow release and the attack does seem to be similarly less affected by the release network.

However, at the fast and medium release settings, the receiver gain literally oscillates at a rate that seems to be a function of attack and release time constants, manual RF/IF gain setting, AGC gain setting and signal strength. The depth of this gain modulation is affected by AGC and RF gain. In order to get stability, it seems that I have to slow down the attack (and/or release) time constant and carefully tweak the AGC gain between the onset of oscillation and receiver peak distortion caused by not enough gain reduction.

Have I completely misunderstood the meaning of attack/release speeds? My 'ideal' attack circuit has a R-C time constant of 1 ms, which means it will even respond substantially to 1kHz modulation. That seems high. The R-C time constant for my target fast release of 30 ms means that it will substantially follow a 30Hz signal. I have had to pad these out to ~20ms attack, 50ms release for stability or tolerably low gain oscillation depth

at medium and lower signal strengths. With this slower attack, stability is much improved with the 500ms medium release speed.

The target attack/release of 1ms/30ms is not good for AM reception anyway as it causes considerable distortion on heavy bass modulation - it is for data services on steady carriers, e.g., PSK, FSK, DRM. But if the AGC causes oscillation, then that's interference of another kind that would adversely affect error rates. Several, including myself, have noted that DRM SNR is improved by defeating AGC, on a wide variety of receivers.

Is this a typical problem for receiver design? Would 'hang' AGC stabilise the AGC loop? Are my design objectives reasonable?

Comments from experienced radio designers/builders/experimenters much appreciated.

Tom

This sounds like a classic negative feedback oscillation. You sense the signal is too large, so you send a signal to kill the gain, and then you sense the signal is too small, so you send a signal to increase the gain.

Having different attack and release time means you have two different time constants My guess is the quick attack leads to the instability, since it is the lesser damped system. If this is true, then you should concentrate on the attack time, i.e find how slow it has to be for the sytem to be stable.

Of course this is really had to do without seeing the circuitry in action.

I've simulated a circuit and a little confused... If I have an BPSK RF signal at 1KHz, and I mix it with an LO of .9KHz, then I should get 100Hz still in BPSK format? PSpice says otherwise. If I filter the IF for lowpass at 100Hz, it doesnt look like anything I could possible work with and doesnt sync to anything. If I pass everything below 200Hz, it looks more like a sign wave, that's syncronous with the modulation.

On the other end of the spectrum (no pun intended), if I went with direct down converstion, what I get at the output of the mixer is a sign that it twice the RF freq that' shifts 'dc offset'. Should I be filtering for the DC offset?
Does anyone have a link to actual waveforms that I should see in a typical IQ demodulation scheme? Or at least some good docs for understanding the waveforms and what I should be looking for?

When mixed down to 100 hz, will there be enough bandwidth at that frequency
for the BPSK to work ? I have no idea but it does take a certain ammount of
bandwidth for a given ammount of data. Also are the components of the
circuit of the correct value to pass frequencies below 100 hz ?

It depends on your newsreader. Generally you just put multiple
newsgroups in the "to" section. Your newsreader will automatically post
to all the groups, and the item will carry that information.

I could be mistaken, but I think "cross posting" would be to enter a
separate post to EACH newsgroup thread, separate from any other newsgroup
thread...

This avoids the following:
Including multiple newsgroups in the posting of a single post--causes any
reply to that post to be sent to ALL the newsgroups that single post has
been posted to...

Warmest regards,
John

I agree with you and slowing the attack is the only way that I have been able to approach stable operation with a fast release. But 20ms or longer attack runs counter to what I understand to be the objective - an attack speed of less than 13 ms and ideally about 1 ms. So, unless I have this wrong, how do other receivers accomplish similar speeds without self-oscillation?

The way my circuit operates (I think) is as follows (I'd be happy to send a schematic to anyone who is interested) :
a) assume an impulse of signal of duration very much longer than the attack time
b) the rectified signal is filtered of RF by a series-parallel R-C attack network whose adjustable output feeds an emitter follower
c) the emitter follower pumps current as a low resistance source into the release R-C network so the attack is not greatly slowed - its output feeds the AGC driver amp
d) at some point, equilibrium should be reached - the current flow through the release resistor and AGC driver base should equal the flow though the emitter follower - but maybe the emitter follower pinches off and that could be a cause of instability?
e) the signal drops, the attack network discharges at attack speed and shuts off the emitter follower, so the release capacitor discharges through its parallel R at release speed, the voltage to the AGC driver falls so the AGC bias rises at roughly release speed to increase RF/IF gain.

Having written that out, I have an idea or two I will try.

Tom

Which is basically what you want ... all the newsgroups being involved in the conversation. When you cross post, most newsreaders can recognize that and mark the posting already read in the other newsgroup. While not everyone may be subscribed to all the newsgroups, a lot of people will if they are related subjects. This avoids them reading the same post multiple times. It also avoids duplicate responses. If you multiply post and get a valid response in a newsgroup I don't read, I may well repeat essentially the same response.

If it is appropriate to cross-post (and it is often overused), then it seems far better than multiply posting essentially the same message to different groups.

Tom,
Another option may be to reduce the gain in the loop. This may reduce
the oscillation without significantly slowing the loop.

Craig

Hi Tom,

You might find some good info from reading the description and
data sheets for the Analog Devices SSM2165 and/or SSM2166
at www.analog.com. They address the issues of having a threshold
which can be adjusted and then varying the amount of compression
or limiting asymetrically. Perhaps you could modify your circuit to
emulate some of these features - or perhaps just use the devices
described?

< Snip >

I don't know receiver design but I have a RX340 that uses the following
settings. Attack is in dB/mS, Hang in seconds, and Decay are in dB/S.

Attack Hang Decay
Fast .8 0 1600
Medium .8 0 100
Slow .8 0 25

Programable attack .01 to 1 dB/mS
Programable hang 0 to 99.9 seconds
Programable decay .01 to 99.9 dB/S

Hi All,

I keep noticing something which looks odd to me - I am sure it is correct because this appears to be standard practice, but I would appreciate it if someone could shed some light on the reasons...

Take a peek at http://web.telia.com/~u85920178/tx/500w-txt.htm (first example I found). Specifically look at the 5 position switch on the output matching, in position 5, the bulk of the inductor is shorted out. This just looks plain wrong to me.

I assume that having shorted turns on an inductor like this drops the Q drastically, or is this the whole point ?

Is the same true for roller coaster type variable inductors ?

Comments appreciated.

Thanks,

Mark.

I don't think Google lets you cross post. You need a real news
server and software to do it.

It might cause some small ammount of power loss but it has been done that
way in many other amps over the years. Probably not enough loss to notice
or others would have done it differantly.

I've pondered this question myself. I've only seen this done on
air-wound coils -- on a coil wound or a core this would be disaster. I
think the reason it's done is because if you _don't_ short the turns
you'd have all sorts of wierd resonance and/or high RF voltage effects
in the unshorted coils.

Tom,

The problem is the system (AGC) is a servo loop and the loop lacks
damping so it overshoots then rings at the loop time constant.

Try adding a simple RC of something like 1000 ohms and 100uf in the
place where your putting a time constant. The high series resistor
will allow fast change but the series capacitor will absorb some of
the rate of change. You may have to emprically tweek the values.

Also Experimental Methods in RF Design (ARRL Press) is a good
reference and has examples plus discussion on the subject..

Mark,

Nominally those coils are loaded to a Q of less than 10. So the
shorted turns do not significantly affect the Q of the coil. Also the
turns are off the "end" of the inductor where the least effect is
felt.

In some cases the shorted turn can be used to tune the coil there
is a 6M amp that used a shorted turn inside the primary
inductor the make the inductance variable with out mechanicaly
altering the primary coil.

Part two of that is if t he unused sections were left unshorted
they may resonate and develope high voltages or other
undesired parasitic effects.

Roller inductors are indeed used that way as well.

Telamon, those are interesting numbers, expressing the action of a more sophisticated, programmable, digital AGC. Classic analog AGC speeds are expressed as the length of time it takes to reach a certain percentage or within a few dB of the desired gain setting, i.e., similar to and based on RC time constants as that was the foundation of the classic AGC control system. With an RC derived control, whether the gain change is 10 dB or 100 dB, it takes the same time. With your digital control in 'Fast' mode, attack would be 8ms for 10 dB and 80 ms for 100 dB; release would be hang time plus 6ms or 60 ms respectively. It's interesting how these compare with my target of 1-13 ms attack, 25-50 ms release.

I'm wondering how your RX340 behaves when you program to 0.01 dB/ms attack, 0 hang, and 1600 dB/s decay (but I see that the programmable decay is limited to 99.9? probably for good reason!). That would correspond to my Fast target when you tune from no signal to S9+50.

Tom

Hi Allison, wouldn't the 1000R-100uF have a time constant of 100 ms?
That would slow my attack speed to 10 times slower than what I think is
the desired range, unless I've got that all wrong!

Thanks for the reference - there certainly is not a lot about this in
the ARRL Handbook.

Craig, the dilemma is that reducing the AGC loop gain results in IF or AM detector or audio overload; increasing it aggravates instability! So far, I can only avoid these two adverse effects by slowing the AGC attack and release speeds to well below what I am aiming for.

It's really not all that hard to estimate what the degradation will be. Use your favorite inductance formula or program to find the inductance of the whole coil, and then find the inductance of the unshorted part if it were standing alone, and the inductance of the shorted part if it were standing alone. From those three values you can find the mutual inductance between the coils, and the coefficient of coupling. You'll probably find it's much lower than you had guessed. The result is that shorting the unused portion really doesn't have that much effect on either the inductance or the Q of the remaining portion.

For example, an inductance program I use tells me that 20 turns of 8AWG wire 2" inside diameter helix, spaced with a pitch of two wire diameters, will give me a coil just over 4" long, 8.705uH, unloaded Q around 860 at 10MHz. (There's some question if the unloaded Q would actually be that high, but that's another topic.) If I use 10 turns of that same winding geometry, I get 3.637uH and Qu about 720 at 10MHz. The mutual inductance between the two 10-turn halves of the 20-turn coil is then 0.5*(L(20t)-2*L(10t)) = .716uH, and the coefficient of coupling is mutual inductance divided by sqrt(L(10t)*L(10t)), or .197. If you leave the unused portion of the coil open, the inductance of the 10t part you're using is, of course, 3.637uH. If you short out the unused portion, the inductance of the used part drops to about 3.496uH, which is only about 3.9 percent. The Q drops by about twice that percentage. But if the LOADED Q of the network is around 10, and the unloaded Q is up around 500, then only 1/50 of the input power is dissipated in the coil resistance, and a change of even 10 percent on the unloaded Q will result in a change of 10 percent in the power dissipated in the coil...so in a 1kW system, the power dissipation in the coil might go from 20 watts to 22 watts, in this example.

In summary, the assumption that the (unloaded) Q drops drastically is incorrect for practical coils commonly used in transmitter tank circuits. But it does suggest that you should understand what the coupling is, and insure that the shorted part of the coil really isn't coupled too strongly with the unshorted part: if the coil is very short compared with its diameter, you'd get into trouble shorting turns.

Cheers,
Tom

>Having written that out, I have an idea or two I will try.

Having encountered a similar problem many years ago, I'll offer
this as a suggestion: Analyze the behavior of the total signal
amplification chain at LOW frequencies, not at the RF or IF
carrier. Know the control characteristics of the AGC voltage
input to the amplifier versus the total amount of gain of the
receiver chain. Approach the whole receiver AGC action as a
low-frequency servo loop (which is what the AGC actually does).
Think servo control systems theory.

Control systems theory is a rather abstract thing and there
probably will be no sudden bright light of understanding
switched on, but here's a bit of that: The AGC loop action
works by BOTH magnitude and phase at low frequencies.
"Nyquist" and "Bode" plots are helpful there, even though

both of those subjects are also rather abstract. In general, if the AGC control action results in instability or even motor-boating, the overall receiver gain - related to the control voltage range - is too high. Adding a voltage divider at the low-pass R-C filter of the AGC voltage input will demonstrate that. Also, the low-frequency phase shifting in the AGC voltage "decoupling" can upset the phase versus magnitude of the control voltage. Note: Vacuum tube or FET RF/IF controlled amplifiers probably use such R-C decoupling, working only on AGC voltage; other amplifier types might have some other form of R-C filtering at low frequencies. That low-frequency magnitude AND phase relationship is important for total loop stability.

What has to be considered in the AGC loop is the response through all the decoupling newtorks between the ACG control source and the controlled device(s). For a "non-linear" loop (separate attack and decay times) that analysis will be difficult. It is much easier to analyze with a Spice simulation that has the capability to model a controlled-gain amplifier. The whole loop at low frequencies can be modelled that way. In starting that, forget the RF and IF components and consider only the amplifications at low frequencies; the source of the AGC control (detector output) may have to be modelled slightly differently in that the detector is, in effect, similar to a power supply rectifier. If that model is tweaked to be stable with sudden transitions on its input, then it will be stable at RF and IF.

Let me add one more general note about AGC design. The BFO frequency is very close to the IF, and it typically puts out volts of signal while the AGC circuit is trying to operate with millivolts. Unless you're very careful with layout, shielding, and balance, a lot of BFO signal can get into the AGC circuit and cause disturbances and malfunctions of various kinds.

The last AGC circuit I did was very conventional, and it's the sweetest operating one I've ever used. But I went to great pains to keep the BFO out of it, and feel that was one of the essential ingredients in getting it to operate so well.

Hi Mark,
If you take an inductor, make a tapping and pass a hugh RF current through the smaller end, then a voltage will be induced in the other side. If the tapping ratio was (say) 10:1 rati,o and 300 volts was developed across the 1, then the bigger end would have 3000 volts at the other end = arcing and "sparkalating", smoke and switch breakdown :-(

The series resistance allows overshoot but, limits it. Also it's
series R-C used in addition the paralle C you have for time constant.
EMDRF is the better source than the handbook.

Roy, you have that right. Simple AGC works well but it's the details.
A 6m SSB design I did required a BFO and balanced mixer (DBM prod det)
to be in a sealed box with bypassed feed throughs. Once that was done
the AGC behaved far better.

I agree on the need for isolation of various circuits but fail
to see the relevance. A "BFO" is on for OOK CW reception and
normally a manual RF/IF amplification control is used to set a
comfortable listening level. Yes, AGC could be used on OOK CW
but it would be a mistake to derive the AGC control from an AM
detector getting "BFO" input...that would be the same as
introducing a DC bias into the AGC control loop...which would
change the AGC servo-action control...perhaps severely so.

Note: A "BFO" source is steady-state. The detector mixes the
incoming signal (usually at the IF) with the "BFO" to derive
the audio. If the AGC control line is picked off this same
detector, the DC component is akin to having a nearly fixed
DC bias inserted. To use AGC on an OOK CW signal, the audio
tone would have to be used...and that necessaitates a different
sort of AGC control source derivation. A peak-riding, perhaps
selective audio circuit could do that, but the complexity of
that part of the receiving chain is growing. It might be
easier all-around to just pick off the IF to a separate AM
detector as the AGC control line source. The "original"
detector could remain as the OOK CW output with isolated BFO
feeding it.

For SSB voice reception, a "BFO" is still present but a single
diode detector all-purpose sort of detector is far from
optimum as a combined audio source and AGC control line source.
It WILL work, but it is non-linear for both audio and AGC
purposes and that alone could be the source of AGC instability.
It depends on the IF signal level at the detector diode (or
"product detector" which is really a mixer stage).

A single diode with large time-constant on its voltage output
is a peak-riding source for the AGC control line. Whether or
not it follows fast "attack" conditions depends on the source
impedance capabilities of the final IF stage. If that is too
high then the "attack" time is slowed from the necessity to

build up a charge on the diode's load capacitance; that can be seen on examining an ordinary AC rectifier circuit in response to a step transient of AC input through various values of AC source resistors. The peak-riding capability is usually distorted on the leading edge...which then reflects on the AGC control characteristics (when loop is closed) in trying to hold the received signal constant at the detector.

Thought of as a servo-control loop, the AGC subsystem can get rather involved and complex, affected by a number of different factors, ALL of which are important insofar as AGC instability is concerned. "BFO" level is just one item and I will disagree that it is a very important. It is no more important than anything else in that loop in my experience.

As a suggestion to anyone else, I would recommend first either measuring or calculating the AGC control line versus both the antenna input level and the IF level at the AGC detector input. That yields a DC baseline datum on the controllable level of the receiving chain. From that, one can "back-track" calculate how well the closed-loop AGC action behaves; i.e., the antenna input RF level versus the peak audio output with AGC on. If that is using old-style "variable-mu" pentode tubes, then the control characteristics will show whatever non-linearity it has steady-state. That can be used as a special controlled-gain model baseline for a Spice analysis of the AGC loop. Differing time-constants IN the AGC control feedback can be set to observe closed-loop response with transient signal input to the antenna.

>The last AGC circuit I did was very conventional, and it's the sweetest
>operating one I've ever used. But I went to great pains to keep the BFO
>out of it, and feel that was one of the essential ingredients in getting
>it to operate so well.

Having had a National NC-57 receiver since 1948, I decided to "play" with it in 1959 and "improve" its performance, such as increasing IF gain. The first IF stage as well as the RF stage were AGC-controlled. Not knowing enough about Control Theory then, nor considering the low-frequency characteristics of the AGC control voltage line R-C decoupling, that modification became a disaster for anything but manual RF gain control. The motorboating (very low-frequency oscillation) extended to having the VR-150 screen supply regulator (gaseous shunt regulator to those of solid-state era times) going on and off. It was restored to its original components and not played with for over a decade. Much later, on having had to get into Control Theory and servo control loops, I could analyze how bad it was and see what I SHOULD have done. The control was too "tight" in trying to hold the audio output too constant over a wide signal input range. There was low-frequency phase shift in the AGC voltage

control decoupling that was responsible for most of the motor-boating; the VR-150 shunt regulator control range was a bit too narrow so naturally it had dropped out of regulation and added the final insult to the original "mod." [forty somethings and younger may not be familiar with such relaxation oscillator circuits :-)]

National Radio Company had made an acceptible product in the NC-57 but it was a low-end item in their product line. It worked well enough as a single-conversion HF receiver but it wasn't optimum in design and no doubt stock logistics at the factory probably accounted for some of the parts values. Several passive components seemed to be rather arbitrary in value choices. I had learned (or should say re-learned) that NO product is an example is "what something should be" as a design example.

There just aren't any "easy" answers for some things in electronics. But, they can be WONDERFUL, challenging "cross-word puzzle" kinds of thing to solve! :-)

I am thinking about building one. Before I start gathering parts I figured I would check to see if anyone has started, fizzled out, or otherwise changed plans to build it. What parts do you have? Any completed modules?

I apologize for not being more precise in my nomenclature.

By "BFO" I mean the oscillator used for product detection when receiving SSB and CW signals. No AM detector is involved. The AGC pickoff is of course done from the IF preceding the product detector, and doesn't intentionally use the BFO or product detector in any way. The problem I was alluding to is that the BFO produces a large signal which is very near the IF, and therefore can get into the AGC circuitry unless some care is taken to prevent it. This produces a DC bias among other problems, which can interfere with AGC circuit operation. I found it necessary to completely shield the BFO, use a good doubly balanced detector, and use differential amplifiers in the AGC chain in order to reduce the BFO crosstalk to a tolerable level.

I strongly suspect that a number of the complicated AGC circuits evolved because a simpler AGC circuit was poorly designed and/or subject to problems like crosstalk from the BFO. Instead of solving the fundamental problems, increasingly complex circuits are developed until one accidentally works correctly, then the improvement is credited to the complex circuit rather than its accidental relative immunity to the results of poor fundamental design. This isn't of course universally true, but it happens pretty often.

I prefer the solution of, "Hmm... there's already a CPU in this radio anyway... and we've got an ADC around... hey, let's make it the software guy's problem!"

>short compared with its diameter, you'd get into trouble shorting
>turns.

Good stuff there, Tom. The COEFFICIENT OF COUPLING isn't
considered enough by others (in my opinion) but makes all
the difference as far as losses.

Toroidal power transformers are going to be in for a hot
time in the old town if they are mounted with a non-
insulating strap. That's the "shorted turn effect" with a
toroidal form having a high coefficient of coupling due to
concentration of flux lines. The conductive mounting strap
will suddenly become very hot being a one-turn winding that
has very low resistance (always insulate such mountings).

Air-core coils having a high length to diamerter ratio will
have a lower possible coefficient of coupling...which
actually varies somewhat depending on the position of the
coupling location along the length...lowest at the ends.
The flux density is very low, spread all over as compared to
a toroid where the flux density is concentrated IN the torus.
"Pie-wound" multi-layer coils have an intermediate coefficient
of coupling, less than toroids but greater than high L:D
solenoidal windings.

There will be some losses due to that "shorted turn effect"
but that hasn't unduly bothered high-power transmitter
designers and users for over six decades. I got started
in HF communications in the Army in the fifties and one of
my tasks was changing the shorting link assemblies on a 15
KW Press Wireless transmitter running FSK RTTY. Two tank
coils about four feet long and about a foot in diameter using
tubing about 3/4" in diameter (memory may be short on the
exact dimensions, I didn't take notes due to having to QSY
as quickly as possible when so ordered). Those got thermally
HOT sometimes but then the final amplifier compartment was
generally thermally hot all over despite forced air cooling.

At least 20 KW of the AC electrical feed of about 45 KW
was wasted in various forms of HEAT on those critters.

Shorting bars were ALWAYS placed beginning at the bottom end
of the coil. A similar shorting system was used on the
old BC-340 power amplifiers (10 KW CW, also running FSK).
Those beasties were operating 24/7 and cranked out the RF
continuously until another QSY was required. BC-340 was
water-cooled with the water flow going through the tank
coil tubing from the final amplifier tube jacket. Was
thermally cooler than the PW-15.

For those who are interested in details and comparisons with
actual result numbers can consult with almost any old text
for ways of measuring Q, coefficient of coupling, etc.
Hours of drudgery to derive all that...as lots of EE students
can testify to. :-)

Sounds good to me. Separated, isolated detectors allow one to
concentrate on the particulars of each, makes it a lot easier to
work with.

For what it's worth on the audio-output part, I'm more fond of
rather high levels of IF into the detector to get around the
"square-law" response...looking for a better AM envelope
reproduction. While that results in better audio, it also makes
decoupling more difficult to avoid feeding the strong IF back
to the input. Different problem, same cuss-words on the bench,
though. :-)

I agree with you there. At least for voice-band detection
receivers (of which I've only built two in a half century from
my own design). Discounting copies of "All-American Five"

table-model cheapies using a single diode for both audio rectification and (low-pass filtered) for AGC voltage to a single controlled variable-mu amplifier. Ultimate simplicity for reasons of price over the counter. One CAN put a BFO on those (Hallicrafters did back in the late 40s) but the performance is not the best.

Separating the "detectors" by function is best. The audio "detector" (I still think of them as 'rectifiers') can be optimized for best sound. The AGC detector can be optimized for its action separately...and its response versus IF input and overall receive chain amplification tailored for the AGC control-loop "gain." Filtering-decoupling that follows can be figured out to keep the low-frequency phase response from upsetting the closed-loop AGC control.

Separate AGC and voice detectors lets one play around with "attack" and "decay" time-constants with no more than a single dual op-amp shaping circuit...multiple time-constants under manual control if desired, that won't interfere with the audio detection part. AGC detector input would have to be the fastest-responding (to desired time-constant) with a relatively simple op-amp doing the time-stretching.

Some folks might consider that op-amp addition "complicated." Won't blame them if they do. From my experience, a "complicated" AGC subsystem is having to AGC on a 1 uSec pulse with a time gate in the presence of other assynchronous 1 uSec pulse sidebands located on 1 MHz intervals (up to 3) on either side...with a decay to attack time ratio of about 1000:1. :-) Did that for an R&D airborne system at RCA...was somewhat too much but that allowed a greater simplification for a following generation of airborne equipment. A lesson there can be to "cover all bases possible" the first time around, then investigate to see what can be simplified for something less complicated.

AGC, in the basic consideration, should begin as a control loop. From there on its a matter of choice of circuits.

Thanks to all for the constructive and informative discussion. I wish I could say that it has helped to solve my problem but I'm still wrestling with it. The low frequency circuit analysis by Spice, Bode and Nyquist plot are beyond my capacity but I have had some excellent help from Dave, off-list, who eye-balled the DX-394 schematic and my mod. We identified decoupling networks and what I assume to be AGC 'delay' networks and tackled it on the basis that reducing the time constants of the larger ones should reduce the low frequency phase shift that could be contributing to the problem. The opposite occurred - increasing the 'delayed AGC' time constant reduced the instability and effectively slowed the attack, especially on the RF front-end. More or less the same effect was obtained by slowing the attack in the attack network that affects all stages.

I believe 'delayed AGC' means a slower or delayed attack at the RF stages; in the DX-394, there is a R-C network adding maybe 15 ms to the attack on the AGC line affecting both the 1st mixer and the drain-source current of the RF preamp and a second network adding maybe 10 ms on top of this affecting the AGC gate of the RF preamp. I've doubled that first time constant and doubled what I would like in my attack and release networks in order to get the fastest stable speeds which I guess would be on the order of 20-40 ms attack and 50-80 ms release.

My mod has a FET amp/buffer at IF driving the heck out of the diodes so that should be fairly linear. I have adjustable gain at the output of the detector/attack filter. I don't think BFO interference is an issue; I don't notice any great difference in stability with it on or off - there are separate envelope and product detectors.

I'd welcome any more input. The base DX-394 schematic is at http://www.monitor.co.uk/radio-mods/dx-394/dx-394.htm and I'd be happy to send anyone the schematic of my mod.

73, Tom

Tom,
I haven't been following this thread. However, in my understanding,
'Delayed AGC' doesn't refer to a time delay. It normally means that the
AGC in the RF stage doesn't cut in until a certain level of signal is
reached. AGC is applied as 'normal' to the IF stages but the RF stage is
held at maximum gain until the input signal is higher. The effect is to
obtain a better signal-to-noise ratio with low-level signals.
Ian.

Would that be the DDS controled receiver design from the UK?
His DDS-Micro design was in an ap-note on the Analog Devices
web site (pdf download), but source code wasn't published.
The specific pic micro he used is now obsolete, though similar chips
are available (require software changes). Also the AD9850 dds
chip he used is now somewhat long in the tooth.

I am considering building a DDS vfo for a homebrew xcvr, but
I am looking at using one of the AD9951 series chips. These clock
to 400mhz and have a 14bit D/A vs the 10bit in the 9850. Spurs
and phase noise should be quite a bit lower with the 9951 series
chips over the 9850. You will need a surface mount to .1 mill
spacing proto board to hand solder it (not to mention good eyes
and/or a strong magnifier, and steady hands). Such proto boards
are available on ebay sometimes, and can also be found for sale
via a google search.

I would also switch from the PIC processor
to an Atmel MegaAvr mirco. The MegaAt16 and MegaAt32 processors
are available in 40pin dip and 44pin surface mount packages. They
have 28 i/o pins available if the on board JTAG interface is used
for debugging. The JTAG feature and the support of the GNU C
compiler makes these chips a better choice (IMHO) than the pics.
A JTAG interface from Atmel sells for $200, but 'clones' are
available for under $50 (and plans are available for building
your own for even less. I have already built one). Atmel's
Avrstudio is a free download for Windows (to drive the jtag)
along with WINAVR (the gnu compilier and C library). Similar
software is available for Linux from GNU/Sourceforge.

>
Most commerical receiver designs that used band switched coils
had a special rotary switch that shorted out all the unused coils
while they unshorted and selected the coil for the current band.
The reason was to avoid 'suckout' at the resonate frequency of the
unused coils.

Be aware that even if you do short out the unused section of the
coil in a tank circuit, if the lead lengths and the switch form
a resonate ground loop you will have arcing while you tune up
on some bands. Been there done that! (2kw amp with a pair of 4-400A's
in grounded grid. Selecting a good bandswitch is VERY IMPORTANT!!!!)

Here is a way out solution.

To avoid the pumping try the following as a last resort:

1. Increase the agc filter cap. value. This by itself will decrease the agc attack time, but if you lower the charging source resistance you can again decrease the attack time. This change may require two emitter flowers in series to lower the charging source resistance. (If 2 x .7 volts is two high of an offset try npn followed by pnp or select the optimum fet.) The object is to move the filter corner down in frequency and stop the pumping. At this point you have fast attack and very slow release.
2. Now add a second agc circuit in parallel with the first. It should have the attack and release times that you want. Compare the two agc voltages and when the second one is lower than the first by some small amount, activate an active pull down to discharge the large cap in the first agc filter.

This may be one way to isolate and stabilize the agc feedback .

I've been running a 9951 overclocked at 600 MHz (It'll do a bit over 700 before it REALLY doesn't like it) Waterproofed in the shielding department, feedthru decoupled and on a 2 layer board with PTH copied from the AD proto board. BTW, the 9951 is still running cool at 600 MHz (External LO) with the center post solder grounded to a large PTH.

Seven pole band pass filter, also in the DDS box. Phase noise is non-existent. Spurious, while at the AD specs is still objectionable.

FWIW, the manual calls it a HP Nr. 2090-0032 with an errata sheet
changing it to 2090-0031. They've probably changed numbers several
times since then.

Thanks, I'm collecting as much of this information as I can and creating
a database to post on one of my websites. I know some products go
though a number of changes as design changes are made. Sphere has some
CRTs in stock, but a lot are listed as "sold".

I will have some Teflon insulated, silver plated stranded 22AWG wire for sale. It is 5 fifty foot rolls (250 feet total)
At least five different colors. The wire is rated at 200C and 600V.
Price at Rochester hamfest will be $7 per pack of 250 feet. I will be in at Flea market Saturday morning. (It is a flea market and I will be wandering about at times looking for stuff that I need) So I will try to be there "on the hour"...

If you could use larger quantities you can reserve 1000' spools of 22 AWG teflon wire for $20 per spool. You must contact me in advance with your callsign. I will be limited by weight and space requirements.

2703. Garmin GPS to TinyTrak3 problems

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-05-31 00:06:59 UTC
From: Anonymous <jupiter@anon.com>
Message-ID: <1117498020.376799@cswreg.cos.agilent.com>
Source record: 18736

Hi, Everybody,

I am trying to set up an APRS station consisting of a Garmin GPSmap 60 and one of the TinyTrak3 TNCs. However, the green 'GPS Valid' LED never lights.

I can connect the GPS receiver directly to my computer's serial port and read good data, and I can capture some of that data and play it back from computer to TinyTrak and the green LED lights up, but a direct connection between GPS and TT just does not work.

I see a waveform coming out of the GPS serial (J2 pin 2 of the TT) using a scope. Quiescent voltage is -5V, and when the data burst comes it is -5 V to +5 V.

Could this be a voltage level problem on the serial? Is there a converter that can be used? Or is it another problem, possibly protocol-related?

Any ideas?

Thank you,

Al W6LX

OK Al, I'm going to go out on a limb here. The GPS doesn't work on
the TNC. It does work on the PC. The PC can send GPS data it
recorded from the GPS out to the TNC and the TNC recognizes the dya as
GPS data and interprets the protocol correctly (the green LED goes
on). You measured the waveform from the GPS and it shows +- 5V.

I. The GPS is good, it works on the PC.
II. The PC is good, it reads and writes GPS data.
III. The TNC is good, it reacts correctly to the PC and the GPS data
from the PC.
IV. The GPS waveform is +- 5V.

My conclusion: The voltage is too small for the TNC to recognize.
Did you 'scope the PS serial data? If you do, you will see that it is
+- 12V. The PC's serial port can read and write both +-5V and +-12V
levels. You need a level converter to change the GPS data to the
level that the TNC needs to see.

Thanks for the reference, Bill. I did learn something of value from it but
the devices are clearly intended for audio frequency although one might
actually support 0dB gain at 455kHz! However, they are a closed loop system
and it's not obvious that one could bring out the required control voltage
to drive the receiver AGC.

Regards,

Tom

I have struggled with this in the past
It is a function of the behaviour of the servo loop at low freq and I
dont have the theory to analyse it properly.
However, the most successful AGC system I used in a DC receiver had a T
attenuator as the control element, consisting of resistors on the
horizontal arms of the T with a Darlington pair to ground as the control
element. This was driven by Opamp -> rectifier (BE junction of a 2N3904)
driving an emitter follwer driving a conventional RC circuit. It seemed
that when you got rid of any DC shift in the system this fixed the
problem. As a bonus you got a surprisingly accurate log detector(over
about 60bB range) for an S meter. The difficult part in all systems
seems to be the control element.

Al-

Russ may be right about needing level conversion. Another possibility is
that you need a null-modem adapter in the line between the GPS and the
TNC.

And what about baud rate? What if the PC has automatic baud-rate
adjustment and the GPS & TNC don't?

It's not just the cost of travel, Rob, it's the time it takes. Just to get to Thurso on the mainland of Scotland takes two ferries and one days travel. I could fly from Kirkwall to Aberdeen but at the prices they charge (350 pounds return) it would be more expensive than the UK-USA air fare. <vbg>

I live about 120 miles from Tulsa. If I had my way, then I'd be off like a
shot to Thurso or Aberdeen or Kirkwall or even Inverness. I really, really
like Scotland, but I'm sentenced to Oklahoma, and I try to take it like a
man.

>I have struggled with this in the past
>It is a function of the behaviour of the servo loop at low freq and I
>dont have the theory to analyse it properly.

The "theory" part should be evident to anyone who has made
a negative-feedback amplifier, single transistor to op-amp.
Getting to know op-amp responses both open-loop and closed-
loop (with negative feedback) can be helpful. Note that
op-amp designers actually build in open-loop phase shifts
at high frequencies to avoid oscillation with feedback.

The only difficult part is in MEASURING the PHASE at low
frequencies in the 0.1 to 10 Hz range...especially that of
the AGC control-line (feedback) circuitry. If not, some
dog-work on analyzing the magnitude and phase response of
that circuit will show that. [ability to handle complex
quantities is preferred there]

If the phase response is 0/360 degrees between AGC control-
line input and output (to the gain-controlled stages), AND
the closed-loop gain of the system is greater than unity,
there be troubles there! :-(

To get a view into AGC behavior with any general receiver,
disconnect the AGC control-line from the gain-controlled
stage and substitute a small variable DC source for the
AGC control-line input to that gain-controlled stage.
Using a reasonably-well-calibrated RF source, pick some
RF levels over the expected dynamic range of receiver input.
At each input level, adjust the DC control-line substitute
to be the same as the value of the disconnected AGC control-
line. Measure the DC value of both the input and output of
that AGC control-line circuitry.

The reason for doing that is to remove any phase effects
at low frequencies. That's a baseline value set that
SIMULATES the closed-loop control range of the AGC.

With enough RF input signal levels, the characteristic curve
of the closed-loop AGC action at DC can be seen...from no
AGC (maximum receiver gain) to high values of AGC control
(essentially minimum receiver gain). That will show the
delta of tiny AGC-control line variations which is the

equivalent of the "feedback percentage" of a negative-feedback amplifier simple formula.

Alternately, one can do an open-loop gain measurement using a series of AGC control-line value increments from minimum to estimated maximum. Setting the simple DC supply (substitute for the AGC control-line) to those increments will do it nicely. Log the RF input level for those DC increments and measure the input to the AGC control-line feedback circuitry (even though it is disconnected from the controlled stages). That will result in the same input signal characteristic curve.

Either way will result in "seeing" what the RF input signal characteristics are, allow one to use the AGC line for things like an S-Meter indicating circuit, squelch control, etc. Note: The alternate method can also be done analytically on paper if the controlled stages' gain v. control line is known. A "gain budget" can be tabulated of the total receiver sensitivity to various RF input levels that produce various AGC control-line values.

That takes part of an afternoon's bench data logging, dreary though that may be. It will establish THE characteristics of that receiver, valuable reference for later work on it. That curve will be no different than that of a single amplifier stage with varying amounts of negative feedback.

Next is to either measure or calculate the low-frequency magnitude and phase characteristics of the AGC control-line circuitry (ALL of it, even to bypass caps at the controlled stage input connection). Magnitude alone will yield the feedback percentage of the equivalent negative-feedback amplifier. The phase response at various low frequencies has to be compared to the "attack" and "decay" times as desired. THAT is not intuitive but must be examined to see if the low-frequency AGC control characteristics will result in a negative-feedback or positive-feedback (oscillatory, motorboating) amplifier equivalent.

A stable receiver WITH AGC should ALWAYS have some error.

If actual low-frequency oscillation occurs, one cure is to attenuate the AGC control-line range. A voltage divider if the AGC control is through voltage does that. Such attenuation works on the magnitude of the AGC control but will also affect the phase.

I hope this simplified explanation is a help for all who aren't familiar with Control System theory. Control Systems aren't as intuitive as many instructors on the subject claim so there isn't a lot of literature on it in popular publications for hobbyists. Those usually present some

very simple analogue such as the ball governor valve on a
steam engine of old and let it go at that. :-(

Waterproofed? Ya liquid cooling it?!!
I've got a small proto board to change from the small surface mount
pattern to a .100" through hole pattern so I can bread board with
the 9951. There isn't any provision for the ground on the bottom
of the chip, so I'd have to add a small square of copper foil to the
proto board, drill a hole in the middle, and solder through the
back of the board to the chip, bringing the ground lead out the back
to the circuit ground.

Are you driving the chip AT 600mhz or using the frequency multiplier
on the chip with a lower frequency drive? What kind of oscillator
is driving the chip? (noise in the oscillator might matter).
> Seven pole band pass filter, also in the DDS box. Phase noise is
> non-existent. Spurious, while at the AD specs is still objectionable.
>

>
I had this idea of not using a low pass filter, but rather a band
switched band pass filter with a separate section for each band.
Might even use a varicap to tune the filter for max output at
the lo frequency via a d/a driven by the micro tuning the dds.
I wonder if such a filter would reduce the spur output over using
even a seven pole low pass?

Lacking a calibrated RF source and much other critical equipment, I do have a 45 year old Eico scope that once belonged to the famous Bach pianist Glenn Gould, and could cobble together a variable dc source and a low freq oscillator. To observe phase response of the open loop system, I'm thinking that the loop could be broken between the AGC detector and the AGC time constant/buffer. Drive the latter and the X input of the scope with the dc supply and superposed low freq signal, feed the receiver with steady state RF carrier and take the output of the AGC detector to the scope's Y input. The variation of the input to the AGC system will cause variation in the receiver gain and the output of the AGC detector. If in phase, the scope would show a line with positive slope; if antiphase, a line with negative slope; if in-between, an ellipse or some open shape subject to time constants and non-linearities. This arrangement would leave the receiver's RF gain control intact and its effect on time constant and phase observable; it appears to modify the discharge resistance seen by a 1uF cap at the RF and 1st Mixer in addition to pulling down the AGC voltage applied to them.

Does that seem to be a practical approach, Len?

For testing purposes, I'd like to make an PC power supply operate when
NOT installed in a PC. I've heard that the AT supply needs at least
SOME load on its 5-volt output before it will operate; is an ampere
or two sufficient?

For ATX supplies, I visited a friendly computer-repair store today and
examined the "cheater" into which they plugged UNconnected ATX supplies;
it had three pairs of connections:
1) A jumper from Ground to PS-ON
2) an LED and resistor from PowerOK to Ground
3) two wires from +5V and ground going into something about the size
of a small box of matches which was shrink-wrapped to the cable

They wouldn't let me disassemble it !-)
Was there probably a 5-ohm resistor in that box?

Most all computer switching supplies need some load on it to start. About
1/2 to 1 amp should be fine. YOu can use a 5 ohm resistor rated at 10 watts
or so to put a load on the 5 volt line. When testing an AT supply I usually
just hook up to an old hard drive.
If you have some kind of load already hooked to the supply they you can
forget the resistor load.

Using PC power supply for powering other circuits than PC
PC power supplies are specifically designed for PC electronics.
Typically they work well in the current range a typical PC takes. If you
take too low current form the ouputs, the power supply myght not work
properly. If you load only one output, you might run into troubles of
poor regulation. Typically PC power supplies regulate the output voltage
of all outputs according the voltage in 5V output pin. If you don't put
enough load to +5V output, you don't get stable +12V output from the
power suppply.

I found the above, on the web, hope it helps...

Warmest regards,
John

I recall about a year or so ago, one of the ham magazines had an
article about converting PC power supplies for use as a radio PS.

Might be CQ or QST. The article gave specs on what youe are looking
for, but I do not remember details. If you are an ARRL member, you can
do a search on past QST articles on their website.

Happy trails,
Gary (net.yogi.bear)

Hi Myron, how's the new QTH going?

Plug in an old HD. It should provide enough of a load to get the PS
started and regulating.

2727. Re: Garmin GPS to TinyTrak3 problems

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-06-02 03:30:20 UTC
From: Anonymous <jupiter@anon.com>
Message-ID: <1117683022.521979@cswreg.cos.agilent.com>
Source record: 18660

Thanks to all who replied. In the end, I never got it working. It appears to be a basic incompatibility between the Garmin GPSmap 60 and the TinyTrak3. I should have done better research into exactly which GPS models are compatible with the TinyTrak3.

An exhaustive search of the Internet turns up absolutely no information on incompatibilities between the TinyTrak3 and the vast number of GPS units on the market today. But neither could I find any complaints of people running into incompatibility problems. Strange.

Incidentally, the latest generation of Garmin units have only USB ports, no more serial ports. By definition, all of these are incompatible with the TinyTrak3.

I have a feeling that the TinyTrak3 hasn't kept up with the times and if it expects to survive it has to be updated to allow operation with the latest NMEA protocol version and the new USB units.

The TinyTrak is a good idea. I hope it gets updated, and I hope to see a section on its web site with information about which GPS's are okay and which ones to avoid.

Regards,

Al W6LX

>Does that seem to be a practical approach, Len?

If that tells you what you want to know, it is practical.

However, the phase information from that Lissajous display is
rather gross. If, with a closed-loop condition, there is
marginal stability, then a better handle on phase response
would be necessary...or just reducing the AGC control-line
magnitude (which would offer less AGC action).

I'll have to presume the Eico scope doesn't have a slow sweep
rate. If that scope has a DC input on both horizontal and
vertical, then the cobbled-together low-frequency source could
be built with a ramp output that would act as the horizontal
sweep; the display would then be just one cycle but that would
indicate the phase difference. Suggestion for source: Exar
XR-8038 DIP which has both square-wave and sine outputs.

A "bounce-less" switch circuit can be put together out of two
NAND gates connected as an R-S flip-flop, an SPDT switch
grounding/earthing one input on each NAND gate. That simulates
a very extreme "attack" situation to check the response of the

AGC control-line circuit. It's a bit much to infer anything of numerical value out of that, though, since the amount of analysis of the waveform out of the AGC control-line is lengthy and probably more time than it's worth.

I'll have to remind all that a reasonably-calibrated RF signal source is also necessary. That will yield both the open-loop gain and the closed-loop gain...which can then be applied to a standard negative-feedback amplifier formula. Even with a "cheap" RF signal source, an RF output voltage meter circuit (even if a 1N34 diode rectifier is used, good to ~ 30 MHz) will provide a maximum RF output level. Resistor Tee or Pi pads built on DPDT switches (cheap slide switches work out best due to least internal inductance) external to the RF generator are effective although not to the wideband accuracy of the waveguide-below-cutoff type used in older commercial RF generators. A sequence of 1, 2, 3, 5, 10, 20, 40 etc db pads would do well enough. If needs be to make the pads the most accurate, a spoiler pad of around 10 db at the start of this chain of pads would insure a good source impedance. While not of greatest metrology quality, those would be better than nothing at all.

Note on the above: The RF signal generator meter would determine the signal level into the attenuator chain. The chain's output would then be that value minus the total db of the attenuators switched-in. Making the attenuator-switch mountings in-line in an outboard long metal box having 1:2 ratio of width to height will reduce most of the RF feed-around across switched-in attenuators; if that is 1 x 2 inches it is roughly high C-Band waveguide size and a maximum of 30 MHz RF input would certainly be below cutoff frequency of that "waveguide." Attenuation through that long metal box would be a linear relationship of db v. length. I did just that with an old Heathkit RF generator (meter calibration set against lab equipment) and outboard switched attenuators...until I lucked-out and obtained a pair of HP 355 step attenuators (wideband to 500 MHz, easier to use).

Unfortunately, whereas "RS-232 and NMEA" are very much a standard, the newer GPS receivers with USB ports neither all show up as a "standard serial-type device" nor do they encode NMEA the same way. :-(Updating the TinyTrak to support USB receivers is a _major_ undertaking... whereas you can talk RS-232 with any old microcontroller (especially at the 4800bps that NMEA typically uses), I believe that the commercial USB receivers are running full speed (12Mbps) and there is simply no way to build a full speed USB master (what you need to talk to one of these receivers) in software alone. I.e., the TinyTrak would have to change to incorporate a microcontroller containing a USB _host_ (and these are few and far between -- Cypress has one), or it would have to add a separate chip to perform this function.

OEM GPS modules that spit out RS-232 won't be going away any time soon; even in 2010 you'll still have no problem getting them.

The scope does not go below 10 Hz sweep. I have a simple gen board that can
be pushed to 3 Hz and maybe lower with mods.

I think you are onto something here regarding the quick hit, i.e. closed loop step response. Use one of those RF detecting scope probes or just look at the envelope detector.If the envelope is ringing, you need more delay. The step can be off to on for attack and on to off for decay. It seems to me it not a matter of what you want, but rather what is stable.

Hi, all concerned:

If you'd like to sell a homebrew and/or kit project which is gathering
dust, send me its original intention, a picture if possible, its weight (for
ground shipping estimate to 45251), and what you'd
like to get for it, and maybe we can shake hands and do business.

Tubes or transistors -- doesn't matter.

TIA and

USB <---> Bluetooth are very common and quite cheap - getting to RS232 might
take a bit more research.

AFAIK, there aren't any simple "microcontroller to Bluetooth" interfaces
available either. I forget the exact chip, but I'm fairly certain the
TinyTrak 3 uses some little 8 bit microcontroller with probably no more than
"many kilobytes" of flash ROM and "a handful of kilobytes" of RAM. That's
nowhere near enough to support Bluetooth.

Bluetooth is also a lot more power hungry than a wired connection would be,
and of course is prone to interference since it's operating in the 2.4GHz ISM
bands.

Hi.
I'm doing some RF experimentation and I need to know the "relation"
between dBm specificatons and voltage level for a signal.

I have a RF mixer with a specification that says:

LO drive level (50 ohm) = -16 dBm

And I have a LO source that give me an output of 2.5Vpp to a capacitive
load of 5pF at 40MHz.

How can I relate both items and design a circuit to connect LO source
to RF mixer ?

If you have some web source to study about this items, I'll be glad to
hear about it.

Thanks

Hernán Sánchez

This is pretty good, but errs when it states that 0 dBm is 1 mW in a
50 ohm system. This is the usual case, but it could just as well be
70 ohm, 600 ohm or 6 3/8 ohm.

Thanks to all who replied. I HAVE now gotten an AT supply to run
outside of a PC (by putting a resistor across the +5/ground wires;
someone else suggested using an old hard drive, which sounds even
easier!-) but haven't yet tried the ATX. But from the "cheater" I
know the ATX connector needs a ground connected to "PS-ON".

Hern�n S�nchez

To rejoin the real world, take the "16" figure and divide it by 20.
get "0.8"
Then find the antilog of that 0.8 [use normal 'base10' logs]
get "6.31"
This number is a multiply or divide factor that is applied to a 50 ohm 0dBm
reference voltage.
So what is this god like reference voltage?. The 50ohm 0dBm reference
voltage is in actual fact 0.223Vac.
The original number was "-"16 dBm. Just read the minus sign as meaning a
voltage less than the 0dBm reference voltage.
So that 0.223Vac reference value is divided by your 6.31 factor.
get "0.035" Vac.
So "-16dBm" is really 35mVac. This means you have more than enough drive
voltage available from your 2.5Vpp (900mVac) local oscillator signal.

Be very wary whenever you come across dBm figures. There is a minefield of
disinformation out there.
In many cases they are intended purely to obfscutate the reader and prevent
them clearly seeing that the described circuit is junk.
In many other cases they are purposely used as an extra level of abstraction
to sort out the 'RF men' from the 'boys'.
Manufacturers still use the dB concept for historical reasons. It doesn't
effect their sales as the RF people buying their kit carry in their heads
instant dB-V conversion tables.

Don't know about everyone else but all my scopes and signal generators and sources and dc-ac-voltmeters and DVMs and signal probes etc, are marked in Volts and Amps. So that's what I use.
(Someday I'll get round to building a real world 1:2:5:10 50ohm attenuator. I certainly can't buy one :-)
regards
john

Except neither you or Hernan can be sure of this. His source is not
specified to work into a 50 ohm load or present a 50 ohm source
impedance to the mixer (what is really needed). Who knows what the

delivered voltage will be when driving the mixer port?

A measurement is in order. Terminate the source in 50 ohm and measure
the power and/or voltage. If it exceeds -16 dBm, attenuate
accordingly.

It is worse than that, Wes. I fail to understand how a device can be specified as X dB into a capacitive load. Last time I looked, a capacitive load couldn't dissipate ANY power.

Jim, the OP said:

"And I have a LO source that give me an output of 2.5Vpp to a
capacitive load of 5pF at 40MHz."

No dB or dBm mentioned. This sounds like a CMOS device with limited
drive capability. That's why I suggest terminating it in 50 ohm,
assuming this doesn't destroy it, and see what kind of power it can
deliver.

Most likely, a buffer will be needed, although -16 dBm isn't much and
at that level it suggests that this is an active, not passive, mixer
and that it might be driven by a higher source Z okay.

Actually, if it is a CMOS/HCMOS output, it might be better to terminate it into a voltage divider of, say, 270 ohms from the osc output to 56 or 62 or 68 ohms to ground. Many of the common clock oscillators are not intended to directly drive a 50 ohm load. Then an output taken across the resistor to ground will look like it's from a nominally 50 ohm source. You could use a larger voltage divider ratio to get the output down further if desired. If the osc has square wave output, that's likely OK for a mixer input, but if it's not 50% duty cycle, you might benefit from cleaning it up a bit with a tuned circuit, for example. And if the oscillator has a TTL output (rather than HCMOS), you might benefit from returning the voltage divider to the osc power supply, presumably 5V. Beware when calculating the power delivered from the voltage divider to a (say) 50 ohm load; put that load in parallel with the output resistor of the divider to calculate the net division ratio. So the suggested resistors, e.g. with 68 ohm output R, might give you about -8dBm, if the osc delivers 2.5V P-P into the divider, yielding roughly .24V P-P output into a presumed 50 ohm load. -- Also, the oscillator probably has DC on its output, and you might benefit from a blocking capacitor. 1000pF would be adequate. And beware that the osc might deliver noticably higher voltage into a resistive load.

Perhaps the OP could provide a bit more detail...

Also, I'd ask if that -16dBm is accurate...that's pretty low even for active mixers.

Finally, RFSim99 is a nice little free program for playing with linear RF circuits, and includes an "RF calculator" which has a tab for signal levels, converting among dBm, watts, volts-RMS, and volts-P-P for a user-specified impedance level. (I wish that tab had "locks" on the values like the resonance one does, so you could see what power level you get when you load a fixed voltage with various resistances, but you can always just copy-and-paste the voltage to "remember" it over a resistance change.) I always appreciate that RFSim99 has a lot of tools all in one place, and I don't have to remember a whole bunch of different programs, each of some very limited scope.

Cheers,
Tom

>How can I relate both items and design a circuit to connect LO source
>to RF mixer ?

A basic definition that is industry-wide, government-wide, has "dbm" as decibels of "0 dbm" related to a power level of 1.0 milliWatts in a "50 Ohm system." That has become so widespread that specification writers don't always include those words. It is implicit when referring to RF components.

The RMS voltage can be quickly calculated from some identities on the basic formula for Watts: P = E x I. Knowing R (50 Ohms) one can substitute Ohm's Law of Resistance of I = E / R into that to get E = SquareRoot (P x R).

For 1.0 mW in a 50 Ohm system, P x R = 0.050 and the square root of that is 0.2236 so 0 dbm has an RMS voltage of 223.6 milliVolts.

In your mixer specification, -16 dbm is equal to 35.44 mV RMS across a resistance of 50 Ohms.

You can't DIRECTLY use your 40 MHz source value of 2.5 V peak-peak across a 5.0 pFd capacitance because it does not include the characteristic RESISTIVE impedance of 50 Ohms. Power in Watts must be related to the impedance of a load in order to perform "work." [a basic definition of power in Watts is "a unit of work"]

Capacitance across a load will vary its impedance depending on the frequency. For that reason the electronics industry has long relied on a basic resistive impedance to measure and characterize RF components. The result is the very common "dbm" referred to 1.0 mW across a resistive 50 Ohm load...or the characteristic impedance of the measurement

system, both source and load impedance.

To relate your mixer specification to your RF source, you
will have to put a 50 Ohm load across the source and
measure that. If you have some stray capacitance across
that load (inevitable) and know approximately what that is,
you can calculate its effect across a resistance. At 40 MHz
a 5.0 pFd capacitance has a reactance of 796 Ohms. That is
not much but it changes the magnitude of the parallel R-C
from 50.0 Ohms resistive to 47.0 Ohms slightly capacitive.
That's a small change and can generally be neglected for
experimental bench work.

>If you have some web source to study about this items, I'll be glad to
>hear about it.

It's in practically every textbook on the subject of RF
electronics. What can confuse newcomers to RF is the
implicit "standard" which is not always included in
specification sheets. The definition of "dbm" is arbitrary
and probably picked (way back in time) for sake of
convenience in measurement by all concerned.

The reason for picking "50 Ohms" in a "system" is more
obscure and ties into the physics of power transfer in
coaxial cables. That's a curiosity that some can look up
if they are interested but does not apply to how to USE the
"dbm" specifications. To use "dbm" one only needs to
remember the definition and apply simple forumulas for Power
and Ohm's Law of Resistance.

I hope that was of some help to you.

That's common in the RF industry, but many others also use dBm -- for example, it's often used in video systems where the standard impedance is 75 ohms, and others where the standard is 600 ohms. In all those applications, dBm is universally defined and understood to mean dB relative to 1 mW, regardless of the impedance.

I imagine we would both have read Hernans post the same way. I.e that he has some logic running at 40MHz and is seeing a rough 2.5Vpp sinewave on his 50-100MHz oscilloscope via a 10:1 probe. From this I'd also assume we both knew that the logic drive impedance would be a couple hundred ohms at the most and that serious mis-matching was not going to be a problem.
I'd though, suggest he just connects the parts together and see what happens. He's experimenting. Monitoring the results (good or bad) is just part of the due process. Doesn't look like he's got a spectrum analyser, so how can he validate a 50ohm test measurement as exceeding -16dBm?.

His sticking point was specifically about the link between Dbs and Volts. A common, basic electronics question yet surprisingly badly answered by the original suggested link, which started off with the concept of a "dimensionless gain" and went downhill from there using 3 pages of sums. How many radio hams talk to each other about their TX powers in terms of (ISO standard) units of dBs wrt one watt?. Why do the filter tables tell me a Cheb' filter ripple is in dBs when all I want is percent values. Why do my function generators handbooks tell me the sine THD is 0.2% upto 200kHz but beyond that the distortion suddenly becomes an obscure "-30db wrt the fundamental".
A recent EW magazine article for a AC mV meter said the response was flat within 0.0024dB. How flat is that?.

Look at this http://spazioscuola.altervista.org/UndersamplingAR/UndersamplingAR.htm
An excerpt:

A STORY ABOUT UNDERSAMPLING

by Angelo Ricotta - Rome, Italy

a.ricotta@isac.cnr.it

ITALIAN VERSION

In the article "Turning Nyquist upside down by undersampling" by Bonnie Baker, EDN 12 May 2005, are reported two formulae to compute an allowable sampling frequency for undersampling a bandpass signal. I was surprised by that because I have been using the undersampling technique since the late seventies and even wrote a report (Angelo Ricotta, "Some remarks on the sampling and processing of SODAR data", Technical Report, IFA-CNR, July 1983) where I gave two simple and practical formulae to compute all the allowable sampling frequencies for undersampling a given bandpass signal. The report was written in Italian and was known, at least, among the Italian community working on SODAR systems in which a few people and even students utilized my formulae in an unfair way because they did not mention the source. On 10 October and 7 December 1991, also to stop the above misuses, I sent two letters, containing my formulae for undersampling, to EDN Signals & Noise Editor but I never received an answer...

Yes, I should suspect that a lower freq for a high freq tube is no problem... I think why you don't see them ever used at 144 Mhz is that there used to be VERY expensive--you would only pay the money if necessary and there were much cheaper alternatives for 144...

Quite true, Roy. :-)

I restricted myself to "50 Ohms" for a couple of reasons:
As far as "pure" RF components go, 50 Ohms is the Z
characteristic; I didn't want to complicate my explanation.

The TV Cable industry is HUGE and they use 75 Ohms. However,
so many radio amateurs run around snarking on "TV" that it
could have raised a lot of unneccessary babbling in here. :-)
TV cable is digital in some locations (ours is in the SF
Valley of L.A.) and has more TV channels crammed into the
same VHF-UHF space than old analog TV. Don't know the
modulation of my digital TV cable signals, whether it is
wider or narrower than analog channels...but my TV service
crams over 400 channels into the same bandwidth. TV sure
isn't the narrow-band stuff that many hams are used to.

"dbv" (sometimes "dbu" but rarely) refers "0" as 1.0 microVolt,
almost any characteristic. Not seen much in specifications,
though.

The "VU" (for Volume Unit) is an old, old one in the audio
and telephone industry with "0 VU" being 1.0 mW into 600
Ohms impedance. Not only that, the "VU" industry standard
used to call out the indicating meter's ballistic (needle or
meter motor) characteristics! :-)

"dbc" is an often-used term on component specifications but is still a relative term of db in regards to the Carrier of a signal where the noise is called out. ["C" for Carrier]

"dba" is a legal term in the USA standing for "Doing Business As" in local governments that require business licenses. :-)

My apologies if some ISPs show two more postings of my message. When I posted via Google on Saturday early afternoon, Google was interrupting itself with lots of users (?) or something that kept prompting "server error." I've since removed redundant posts on Google, but some other ISPs may be storing the multiples. Stuff happens.

Interesting. I've many times seen dB relative to one volt as dBV, and dB relative to one microvolt as dBuV, but never dBv meaning dB relative to one microvolt, or dBu at all. Do you have any references that show these unusual usages?

Roy Lewallen, W7EL

The 2C39 was never intended for lower-frequency "CW" or other narrow-band modes. General Electric used them in 1800 MHz pulsed microwave radio relay terminals having peak pulse envelope output of 12 Watts...with forced-air cooling on the integral anode fins. There were six 2C39s in every GE 1.8 GHz terminal designed about 1950 (!).

The transconductance is very high (14,000 umho?) and the grid-cathode, grid-plate spacing very small. The only sure way to hold such tolerances in varying heat environments is to use non-standard glass or ceramic tubing sections in the inverted lighthouse structure. Those who want to use it have to have an equally-expensive socket arrangement or be a fairly competent machinist have good tools at their disposal.

The GE microwave terminal used integral socket and tuned cavity assemblies at 1.8 GHz. The GE transmitter was a chain of 7-pin and 9-pin tube oscillator-multipliers to about 255 MHz, then into a 2C39 septupler, that into the 2C39 final amplifier (pulsed anode). Receiver LO had a similar arrangement but only one 2C39 in the chain. "Hot spare" duplicate assemblies for the RF doubled the 2C39 totals. They worked and worked and worked in 24/7 operation, nine terminals where I was the operation and maintenance supervising NCO in the Army. There were hundreds of them used in many kinds of multi-channel radio relay, including long pipeline telemetry and control in the USA.

The only thing "bad" about them was due to another tube manuafacturer's dimensional conflict with GE cavity design.

Why that particular tube? Because it "looks sexy" with the anode fins so nicely machined? There's lots more half-century-old vacuum tube designs available somewhere. Western Electric 416s and 417s are out there in larger quantities. Geez, 829 duals have been used at 144 MHz with more output than one can safely run a 2C39 at that frequency. Socket assemblies for an 829 are easier to

get than for an inverted lighthouse structure.

A year or so ago I happened across a couple of non-USA sites giving nice details of 2C39s used in ham VHF transmitters. Nice photos and dimensions available. Both of them used the triode "pushed" beyond its safe limits of power. Think about replacement costs.

At 2 meters, a better way using vacuum tubes (besides going to Eimac goodies) is in a "distributed amplifier," the grids of many 9-pin tubes connected to an L-C delay-line-like structure, the plates connected to another L-C network. The Tektronix 540 series scopes had those for the vertical amplifiers, good beyond 50 MHz, back in the 1960s. No tuning required...except in how to couple the medium-Z output to a low-Z antenna.

Or...one can get transistors that have worked in their ratings at 150 MHz VHF "business band" with all the nitty and gritty details in old Motorola Application Notes. CW operation at 2 meters no sweat at up to 150 Watts, more than a 2C39 pair can do safely. Lots of alternate choices...such as solid-state Cellular Telephone cell site ("base station") transmitters and equivalents that don't have internal networks to optimize operation in the 1 GHz band. [but, you knew that already, right? :-)]

Gee, I hope Bonnie didn't claim they were original. Certainly it's not difficult to figure out.

More interesting to me is recent work on letting a delta-sigma ADC sample at a rate to serve as a direct IF sampler--up around 5GHz. The practice of getting it to work really right at such frequencies is much more interesting than the formulas for what frequencies work and avoid aliasing.

Cheers,
Tom

Greetings all,

I'm new to the group and find many of the various threads fascinating. I'm currently building a homebrew HF rig.

I think undersampling has probably been around nearly as long as sampling itself. This is because samplers are a subset of (RF) mixers, and early engineers fluent in RF mixer skills would have had undersampling in their toolboxes already.

As mixers, samplers are modelled as a multipliers with the sampler clock serving as the local oscillator. What makes samplers a subset of mixers are the constraints placed on the LO--in the ideal sampler a Dirac delta function is used. This waveform has the property that all harmonics (including the zeroth or DC and even harmonics) have the same amplitude. Our doubly-balanced RF mixers typically respond to only odd harmonics. Real-World samplers approximate the ideal sampler fairly well over a wide frequency range.

Because samplers have a DC response, the baseband signal Fin is passed by the sampler, something RF mixers don't normally do (but can be made to do simply by putting a DC component on the local oscillator). When viewing a sampler as a mixer, aliasing is nothing more or less than the mixing product (LO-Fin) overlapping the baseband signal Fin. Undersampling is nothing more or less than prefiltering the desired band of frequencies and mixing them to baseband with the appropriate harmonic of the local oscillator.

I've not found the notion of samplers as mixers in the literature, but probably could if I looked hard enough. Perhaps authors consider the notion either obvious or not useful, but to this old ham viewing samplers as mixers is useful.

Bonnie's article contains a fun blunder. She states Nyquist and Shannon developed sampling theory in the 1920's, which would have put Shannon in his teens. Shannon's seminal paper on communication theory was actually published in 1948. I've read that the 'Nyquist rate' should really be called the 'Shannon rate' as he was the first to develop it. Anyone know more?

Regards,
Glenn Dixon, AC7ZN

This page: http://decibel.biography.ms/ mentions both dBv and dBu.
Says in "electrical voltage" (probably with reference to audio
industry), dBu and dBv both mean dB relative to 0.775V -- generally
0.775Vrms, but dB taken as 20 log(V/0.775), without reference to a
particular impedance.

But the same page says dBu or dB(lower-case Greek mu: "micro") as radio
power is dB relative to one microvolt per square meter.

Go figure. It all points out the need to be careful to define your
terms if there's any chance of ambiguity. If you're not careful, your
reader may think dBu refers to Dallas Baptist University, or Deutsche
Billiard Union, or Duluth Business University... though the
capitalization would be wrong for those.

Cheers,
Tom

That's absolutely correct.

Tektronix has produced sampling oscilloscopes from at least the early 60's which have a frequency response of from several to several tens of GHz but sample at rates often below 1 M sample/sec. Aliasing? You betcha! As you pointed out, the aliased signal is the desired one -- a frequency (or time) converted signal. The only requirement is that the signal be repetative, since it takes samples from many cycles to create the time-scaled waveform. Single-shot events, often misunderstood or disregarded by RF engineers, require Nyquist-dictated sampling rates. This is done by most conventional digital oscilloscopes. The Nyquist criterion assumes that you want to recreate a nearly exact replica of the waveform and that it extends down to DC; if you'll settle for a time scaled or frequency shifted one, or one with a limited bandwidth, other options are available.

There are a number of "obsolete parts" distributors around the world.

Your part number LM325
http://www1.national.com/ds/LM/LM325.pdf
came up as available
http://www.icparts.com/dbOffers.asp

Rochester Electronics actually purchases the "dies" from many discontinued
IC devices
http://www.rocelec.com/

Summit Electronics also lists this part as available
http://www.summitelectronics.com/searchItem.php

4-Star also lists thousands in stock
http://www.4starelectronics.com/part_search/PartSearchResults.aspx

Thanks, Tom. This newsgroup is truly educational. I'm slowly learning that out there, somewhere, just about every possible convention or nomenclature is used by someone for some purpose. I'll bet I'm the only kid on my block now who knows what dBu and dBv mean. And I guess Len is the only kid on his block that knows they sometimes mean dB relative to 1 uV, as well -- ah, what's a factor of 775,000 one way or the other, anyhow.

dBu = dumb Bastard unit.

I read Angelo's full article (shoulda done that before I pontificated the first time) and it answered the Nyquist vs. Shannon question I had. Nyquist had the concept, Shannon proved it mathematically. Thanks, Angelo.

Hi

Thanks to all of you... like Roy said, this newsgroup is very
educational... now I have enough information to make some
experimentation with this mixer and oscillator... actually, the mixer
is an Analog Devices AD607 and the oscillator is a Linear LTC6903...
I'm planning to build my own rig...

Thank you so much.

Hi Hernán,

Hope a couple comments will be helpful:

I'd suggest you reconsider using the LTC6903. The data sheet says it has a lot of jitter, which will translate to huge phase noise... If you connect up just the LTC6903 and listen to its output on a good receiver, if it doesn't sound like a clean tone (SSB/CW mode receiver) or a noisless carrier, that's what it's going to add to whatever signal you want to listen to when using it as an LO for a receiver. There are probably some very decent low-power LO designs in the QRP community that you could adapt. May be difficult to get wideband digital control, which it looks like you might be trying to get with the LTC part.

I suppose the AD607 is pretty tolerant of levels at the LO input, and it's a relatively high input impedance. You don't have to waste power by adding an external 50 ohm resistor. Get the LO input voltage level close to the suggested value or a bit more and you should be fine.

Cheers,
Tom

Tom,

You might try an rf choke in the agc line near the agc detector. With
fast attack that usually means small filter capacitors on the agc
line. Rf can be coupled into the agc line that larger time constant
capacitors would filter out.

I have also found that decreasing the capacitors at each controlled stage to try and speed up the attack times resulted in instability of stages due to not enough rf decoupling.

As another poster mentioned, using a low source impedance on the agc driver amplifier will allow you to use larger capacitors on the agc line. That can solve most rf on the agc line problems.

Hmm. I used several of these in two-meter receive pre-amps, but never considered them for the finals. I did have a little blower on the 416B tho.

I know that W-E used them in transmitters but I never saw any ham designs doing it.

Had one of those on two-meter CW/AM. Used the modulated high voltage out of my Heath DX-100 to run it.

The 2C39 is often converted to water cooling, and really pushed.

I've used them aircooled at 432 but thy are only good for maybe 15W
that way. A pair running grounded grid at 144 would work but for the
it's a lot of work unless you go to the trouble of water cooling. I'd
use 4CX250 before I'd bother with that.

FYI the motorola H44s (a old tube UHF FM business radio used 2C39s for
the driver and final).

Wes Hayward in _Experimental Methods for RF Design_ bemoans the fact that our transmitters are so dirty in terms of noise floor, close-in phase noise and IMD. I see newer transmitters like the Mark V offer a cleaner class A mode which really seems to help IMD, and read a previous post regarding a transmitter that filters the noise floor, but wonder if there are any homebrewers out there who are working this problem? This seems the type of problem that we hams can and do ignore completely, unless we are contesters or have a neighbor on the bands.

This is not such a big issue at HF where band noise
is relatively high. Keeping noise and distortion to
a minimum is a lot more important on VHF where noise
is low, local stations are very strong and everyone
has an ultra low noise preamp. I can operate within
+/- a few KHz of some of the cleaner local VHF stations.
Some of the nastier ones need about 30KHz of elbow
room.

> any homebrewers out there who are working this problem?

Many homebrewers put a lot of effort into keeping
phase noise and IMD to an absolute minimum. Some
of the cleanest signals on the 80M band can be
heard on the homebrew net frequency (3.727MHz).

Hi, Joel,

Actually, RS-232 has always baffled me, and from some measurements I made it doesn't seem to be a very strict standard. For example, the waveform coming out of the GPS receiver was +/- 5 V, whereas I have seen the waveform out of the RS-232 on the computer at +/- 12 V. Is the voltage level arbitrary?

Al

There really is an RS-232 standard, it's just commonly abused. Here's what I have from a "cheat sheet" I have at hand:

-- Transition levels are between +/-3V (this is what you have to detect)
-- Maximum open circuit voltage is 25V (!)
-- Maximum load capacitance is 2.5nF
-- Load resistance is 3-7kohm (this is ignored all the times -- often the load is much, much higher than this)
-- Maximum slew rate is 30V/us (probably violated occasionally but no one checks :-))
-- Maximum transition time is 4% of bit time
-- Maximum data rate is 20,000 bits/second (obviously ignored with good reason...)

The above is supposedly the official EIA-232 standard, "revision D," approved in November, 1986.

As you can see, both +/-5V (open circuit) and +/-12V drivers can readily meet the spec so long as they still swing +/-3V into 3k loads.

Often times the receivers are designed so that the "logic 1" input is anything below about a voltage or two and anything above that is a "logic 0". This is done (rather than having the threshold at 0V) so that you can get away with hooking a TTL or CMOS logic output directly to the RS-232 input and still successfully receive characters. You'll occasionally see people ask whether or not some given serial card or USB to serial adapter will support such shenanigans. :-)

---Joel

Message-ID: <1118199651.591076@cswreg.cos.agilent.com>
Source record: 18642

Thanks, Joel! This is all very good information. It does bring up another point, though, related to my original question about interfacing the GPS to the TinyTrak3.

The GPS puts out +/- 5 V serial, but the Tiny Trak's serial input is a TTL-level input to the PIC microprocessor. The PIC runs off of a single +5V supply. I guess it can withstand the negative voltage swing without failing? And... if I looked at the serial output from the GPS into an open circuit, there was no signal. It was as if the GPS shut off its serial if it detected an open circuit. Is this normal? Even after connecting it to the TinyTrak, many times it wouldn't 'wake up' and start sending serial data. This was very confusing.

Thanks

Al W6LX

Hello Len and All. Thanks for the replies. I found all of the "positive" responses very beneficial including the Ghz responses. The reason for my enquiry is that I have some of these tubes and related surplus equipment and was looking for a way to use the parts from it. In fact, I believe the equipment I have is one of the pulsed relay stations mentioned below. I have one complete Lo-band unit except for the horn antenna.

It sounds like the end would not justify the means in considering these tubes as viable 2-meter amps. I do have a few 829/3E29's and sockets in the parts box, so that is a possibility as well. Anyway, I like tube equipment which is why I am not going the solid state route.

Thanks again.

You'd have to look at the PIC's data sheet, but it's very common for digital ICs to have appropriately connected diodes to Vcc and Ground for the sake of ESD protection. It's not the most elegant design, but it's not uncommon to use these built-in diodes to limit (clamp) input voltages to a diode drop above Vcc or below ground, which -- assuming the current through the diodes is limited, hence the power dissipated by them is -- is usually harmless.

> And... if I looked at the serial output from the GPS into an open circuit,

I am a little surprised, to tell you the truth, but given that the Garmin is typically battery powered, it would make sense for them to shut down the serial interface circuitry if they don't detect anyone "listening."

-- The maximum distance is 15 m (or was it 50 ft originally). This is
often ignored and usually the problems are related to ground potential
differences.

The 20 kbit/s makes sense, when you look at the other requirements. At
this speed, the bit time is 50 us and a 4 % transition is 2 us. At 30
V/us, that would be a 60 V transition from -30 V to +30 V. Compare
this to the 25 V open circuit voltage.

To charge a 2.5 nF capacitor with the 30 V/us slew rate, a 75 mA
current is required. IIRC, the standard also contained a short circuit
current limit about that magnitude. The power dissipation can be quite
high in the transmitter.

These calculations clearly indicate the fundamental problems with
RS-232.

The RS-422/485 and later LVDS solved the problem by radically reducing
the driver voltage swing to a few volts or even below 1 V. Even with a
modest 30 V/us slew rate, the transition from one state to an other
does not take a long time. With the termination resistance of the
order of 100 ohms, the connection can also be analyzed as a bipolar
current loop. Since the characteristic impedance of a twisted pair

cable is typically around 100 ohms, this is also a well matched (low SWR :-) transmission line system, so there are not much reflections that would mess with the bit transitions. Also the differential construction avoids most of the ground potential difference problems. RS-422/485 is usually implemented with transceivers running from a single +5V supply

It is sad that RS-422/485 is not used in common PCs, but instead all kinds of hacks violating the RS-232 are used (some even claim TTL signal levels RS-232 "compatible").

He has indeed.

But what he was writing about would be something like a method that enables a medium power (tunable, not crystal-controlled) transmitter that, while transmitting SSB, still allows reception of adjacent weak signals from a receiver connected to a nearby separate antenna. At the time of Wes's writing, it seemed clear to this reader that Wes believed this technology didn't exist, at least in the amateur community. Since his writing I haven't really seen the problem addressed beyond what I mentioned in my first post, and I was asking if anyone knew anything more.

You're describing the oscillator phase noise problem, and since G3SBI's unveiling of the "H"-mode mixer, THE compromise to a "perfect" radio.

All oscillators have some degree of phase noise, from a poorly designed VFO, to a well designed one, (One of the better is Gumms class C design featured in several of Haywards books). The DDS has VERY little phase noise, but has substituted serious problems with spurious content in it's spectrum, and use of a PLL to get rid of those results in phase noise again (outside the loop bandwidth)

Lots of folks working on it, the same G3SBI has come up with a multiple resonator VCO for his PLL in the CDG2000. While it has had some technical criticism, Tibor Hajder has established that the concept is theoretically sound and results in a faster roll-off of phase noise than the single resonator approach. (Applied Microwave and Wireless, Oct 2002)

That same problem from the interference caused by the "lousy" transmitter, will be encountered from the phase noise of the local oscillator of the "receiver connected to a nearby separate antenna". Unless of course, the RX is a TRF design with no LO.

Hi.

Thanks for your suggestions....

Yes, I'm trying to do some digital control to the frequency of LO using the LTC part. I will think in another way to do that...

I'm looking for an oscillator of about 33MHz to replace the LTC part... any ideas ?

About the AD607 comment, I have a voltage divider to couple the previous LO output to the level of LO input of AD607... is it what you mean ?

Thanks

>out of the GPS receiver was +/- 5 V, whereas I have seen the waveform out of
>the RS-232 on the computer at +/- 12 V. Is the voltage level arbitrary?

The RS-232 specification formally requires that the voltage swing both positive and negative, with respect to ground, by at least 5 volts. Swings for a loaded circuit can go up to +/- 15 volts, and the swing must not exceed +/- 25 for an unloaded circuit.

RS-232 receivers are required to be sensitive enough to detect reliably at +/- 3 volt levels. Voltages between +3 and -3 are somewhat of a "no-man's land" and as far as I know the RS-232 standard is silent on how they should be interpreted.

The slightly newer RS-423 spec also requires positive and negative swings, but they only need to be +/- 3.6 volts at a minimum, +/- 6 volts at a maximum, and the receivers are required to have +/- 200 millivolt sensitivity. This standard allows for simpler operation from a 5-volt-only circuit (a simpler charge pump can generate a -5 supply), and the increased receiver sensitivity allows the system to work with longer lines (up to 4000 feet, where RS-232 is formally limited to 50 feet).

A lot of devices these days don't produce properly-conforming RS-232 *or* RS-423 signal levels on their serial ports. It's fairly common to see devices which use TTL/CMOS voltage levels - swinging up no higher than 5 volts, and down to ground.

To cope with such nonstandard signals, it has become fairly common to use serial-port receivers which are deliberately asymmetric... they have a single detection threshold, somewhere in the 1-volt range I think. A receiver of this sort will work properly (with a slight reduction in noise margin) with a real RS-232 or RS-423 transmitter which swings to +5/-5 or above, and will also work with a "pseudo-RS-423" transmitter which swings +5/0.

Because I work with high-speed ADCs, I'm most familiar with articles about jitter in sampled systems. A sampler and a mixer are pretty similar, and you should be able to learn a lot from things like Analog Devices ap notes AN-501 and AN-756, and even the data sheets for converters like the AD6644 and AD6645. For example, the SNR for an AD6644 sampling a 30MHz sinewave at 65Msamples/sec is degraded perceptably by clock jitter of 0.15psec, which is about 0.001% jitter, expressed as a percentage of the clock period.

I'd post links to the pdf files for those ap notes, but the form I have them in, they are too long to reliably include in a posting. Just go to http://www.analog.com/en/index.html and enter AN-501 or AN-756 into the search box. Also, if you enter "jitter phase noise" (without the quotes) into a Google search, you'll get LOTS of references.

http://www.maxim-ic.com/appnotes.cfm/appnote_number/3359 is an ap note on conversion between clock jitter and phase noise.

Disclaimer: I have not reviewed any of these apnotes critically for accuracy.

Cheers,
Tom

Yes, a voltage divider should do fine. It may be convenient to have the voltage divider output look approximately like a 50-ohm source, but from what I can see in the AD607 data sheet, there is no requirement that the LO come from a 50 ohm source. You just want to deliver a voltage to the LO input pin which is equivalent to -16dBm across a 50 ohm resistor: in other words, about 35mV RMS or 0.1V peak-to-peak. I expect that if your level is anywhere between 0.1Vp-p and 0.2Vp-p, or even more, or perhaps even a bit less than 0.1, it should work fine. I didn't notice anything very explicit in the data sheet. about it.

Two choices for digitally-controlled LO are DDS (direct digital synthesis) and PLL (phase locked loop). Each has its strong points and drawbacks. Do you want to keep the power very low? What sort of frequency resolution do you want? How simple do you need to keep the circuit? How critical is it that the LO not have any noticable spurious outputs? -- I still suspect that the QRP community has already done some nice work on LOs that might suit your need.

Cheers,
Tom

GM Ed

Well, I can cure your problem, and give you something to cover that hole in the wall at the same time if you'd get busy on a STAR offspring. The alternative frequency to 3.727 is 14.305 or 14.307 when some net is in operation. I've worked 10 STARS up there and have made up a little WAS certificate for guys that have done likewise. So far, Peter got number one, Alessandro number 2 and a really weak contact with DL9 (he was running 20 watts to a field day dipole on a day with REALLY lousy propagation) gave me number 3. (Peter has an endorsement for working 20 of them!)

I know what you mean, we have way too much money over this way (We keep spending money we don't have, THAT will change) and homebrew is a dying artform. I make a lot of contacts where the guy on the other end responds with "yours is the first homebrew transceiver I've EVER worked." My Signal One hasn't been turned on in over a year and thinking of getting rid of it.

There IS hope. After Dayton, we have two more under construction, one in NJ and one in GA.

Regards, County Cork almost got invaded last Spring to see you, but we loved Goray so much, I only made it down to Waterford. You live in a beautiful part of the world.

Melt solder!

Winnie:

You need dynamite or nitroglycerin and a detonator.
Rip out all the insides from the radio and install the dynamite/nitro,
detonator and switch (for the first one the timer will be you)--go deep
into the desert where no will hear--holding the radio tightly--throw the
switch--if all is well and it is working, go build another one for
use... <grin>

Warmest regards,

Thanks, Harold, I appreciate the info and will try to find the article.

Phase noise is but one of the problems Wes mentions, and on the transmitter side he makes it clear the IMD particularly in the transmitter final stage needs work and is perhaps the largest of the problems on the transmitter side. Wes implies that he can actually hear such distortion simply by listening to the band (I don't know what to listen for beyond a particularly wide-frequency signal). Chris Trask has done excellent work on this, but haven't seen actual IMD numbers from his techniques.

I'm currently thinking a poor IMD transmitter would only be a problem in a wideband mode such as SSB or SSTV. Though in theory a poor IMD transmitter might cause keyclicks in CW (I really haven't thought this out), I doubt this is much of a problem.

This posting is from a well-known troll, who delights in stirring up the pot on USENET with outrageous and provocative postings. The Newsgroups: header is the clue - the troll's posting runs are spread across many newsgroups, but each run includes a single fairly-obscure newsgroup, which the troll seems to use to collect and count responses.

My recommendation: ignore such postings completely, and if you do follow up, edit the Newsgroups: header down to the minimum (i.e. remove the name of the newsgroup being used to collect the responses).

I HATE it when I do that! No, it's an OLD term. Actually, one of the few that's older than me. Stands for Tuned Radio Frequency, the topology from before Armstrong came along. Tuned RF amplifiers at the signal frequency, followed by a detector and audio. No oscillators.

IMD, in particular odd order IMD, is readily identified by tuning to the opposite sideband of a SSB signal with a selective receiver. If you can hear the signal weakly but clearly, you're listening to the suppressed sideband of the transmitting station. If everything is garbled, (AND MUCH stronger than the suppressed sideband which you probably CAN'T hear due to the garbage) You're hearing odd order IMD.

If it's a REALLY strong signal, it may be being generated in your receiver. If it's not terribly strong, (Like maybe "S"-9 although this is being pretty subjective) it's likely that the transmitting station is producing the IMD.

We've been sold down the river to some extent, published tests of amateur equipment in this country, now examine the IMD with respect to a single tone of two tones used in the test to generate the IMD. This makes the equipment look like it's 6 dB better than it would be if you tested it against BOTH tones which is the benchmark our military and most other countries use to evaluate IMD. Commercial offerings these days, particularly in more modestly priced gear is really pretty sorry in this respect.

IMD is bad news, but there are cures for it. Phase noise is bad news, and there's no cure for it other than using very High Q sources that still have it but at much reduced levels. New technology that uses spur cancellation in digital synthesis is also helpful, but out of reach for most of us.

Everytime you multiply an RF signal by 2, you increase it's phase noise by close to 6 dB. Everytime you synchronously divide that signal by 2, you gain that same 6 dB. Obviously, if you can make a very low phase noise variable oscillator at a high enough frequency so that you can divide it by a zillion and still have it high enough to do what you wish to do with it, you wind up with a low noise source. That's a bit expensive as well.

IMD should be expressed referencing a single tone of a two tone test
signal. That is the way most tube manufacturers do it.

Some of the radio manufacturers reference IMD to PEP which makes it
look like the IMD is 6 db further down!

The PEP of a transmitter is 6 db higher than either tone of a two tone
signal.
If the IMD is 30 db below the level of one tone of a two tone signal
then it will be 36 db below PEP.

I didn't bother following the link, but the original message
was posted to three completely unrelated newsgroups, the other
two pretty obscure. So I'd say the point wasn't the question, but
to get responses into one or both of those other newsgroups. I gather
some see it as a game, and if you don't get responses in the specified
newsgroup, you don't win points.

So anyone who replied without deleting the other newsgroups was playing
into the hands of the original poster. Those who didn't, like you Roy,
well the poster doesn't care and likely won't see it.

The poster isn't interested in making a bomb, he's interested in
getting responses. The whole deal is to make the post seem almost
but not quite on topic to a newsgroup, so people will fall for it and
reply.

On many of the older tube type base radios, there is a capacitor (like a 4uf) on each the pins of the mic connector...like on a 4 pin mic male connector there might be 4 each caps, wired in series, with a leg of the cap wired to one of the pins with one leg of the caps going to ground.

Question is:
1-why is this done
2-what is this suppose to do
3- if the caps are not used what will be the outcome

Thanx!!

2845. Identify High Current Power Supply Transformer

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-06-10 13:40:59 UTC
From: pinpassion <mjdrum@comcast.net>
Message-ID: <1118410859.300137.78310@g44g2000cwa.googlegroups.com>
Source record: 18577

Hi Gang,

I have a large and heavy power supply transformer
that is part of a high current power supply project
that was featured in 73 magazine back in 1973. It
was started by a ham radio operator and was never
finished. I am going to finish it, if I can. I am
trying to identify the transformer leads. This is
for a 12 volt, 40 to 60 amp output. Here are the markings:

This transformer was made by ADC and is marked 541-010 REV H.
There is a marking on it that says 3-19470 and what I think
is a date code of 7438. There are terminal connections on one
side that are numbered 1 - 6. On the other side the connections
are numbered 7 - 14. I need to know the connection scheme for
this transformer so I can put it to use. I contacted who I
thought was the manufacturer "ADC" for information, and that
did not help.

I don't have the issue of 73 magazine, and I don't even know
if this is the same transformer that may have been part of the
construction article. I can take pictures and post them if that
might help.

Anybody have any ideas?

Thanks a lot.

Mike

I'm assuming rf bypassing but 4uf would be extremely high. That would
bleed off any audio as well.

Ohm out the windings. Figure out which ones are center taps for the secondary or input voltage selects on the primary. (It may have two independent secondary and/or primary windings if center-tapped out and intended to work on both 120 and 240 VAC).

The lowest resistance winding is the high-current secondary. The primary must be one of the other windings (if you're lucky the only other winding is the primary!)

Tim.

It might kill him if he touches the radio chassis when the rectifier fails. The stink is from the gas seleniums give off when they short. Since the rectifier is in the power supply (across the AC line) and has the full line voltage across it as long as the line cord is plugged in (whether or not the radio is on), if it shorts it will likely put the chassis at line potential (until the fuse blows). Another way the guy could do himself in in a big hurry would be to touch the chassis of an AC/DC radio and a grounded surface, such as a radiator, both at the same time. Just a couple of thoughts.

I've never seen a radio where the rectifier is across the AC line. Half wave rectifiers are in series with one side of the AC line with the cathode feeding into the B+ line (thereby isolating that side of the rectifier from the other side of the AC line by the tubes and electrolytic capacitors). Now then, if a bypass or electrolytic were to short out completely, that would put the AC line across the rectifier. At any rate, I've never seen a rectifier that was energized whether the switch was on or not (save some of the cheap SS stuff where they keep the PS live and switch the radio out of circuit).

Hi all,

It's me again, attempting yet another mad science project, and I have practically googled the subject to death before thinking of asking this group for help:

I am wanting to put video (preferably color but will settle for grayscale) onto a UHF TV channel for inhouse use only. I am considering doing it as follows:

1) Convert output of a VGA card to composite video using resistive combiner
(found a few on net).

2) Place composite video on VHF channel 3 using a game modulator.

3) Upconvert the video signal on VHF to UHF by with a local oscillator whose frequence is the difference between the channels. I'd use an active mixer circuit from the VHF/UHF part of the Handbook to do this.

4) To test functionality, attempt to tune in using either an analog TV receiver or a TV tuner card.

Question is this:

Is point 3, upconverting video from VHF to UHF, a generally workable technique?

Any other gotchas or pitfalls to my intended approach?

Thanks in advance,

The Eternal Squire

The easiest way is to gt a hard rubbish vcr, (most have been dumped
because of tape transport faults) use the av inputs, and output on a
UHF channel - the modern ones have tunable UHF output.

Did some research on Alps UHF modulator, these are limited to channels
30 - 37. I am wanting more channel range, but these would be
good for experiments I suppose.

What I want is to ask if upconverting the HF television signal to the
center frequency of the UHF channel would have the same overall effect
as using a direct modulator.. The physics says probably yes, but are
there any showstoppers other than physics?

Converting TV channels - even upwards to UHF - is commonplace in cable
and MATV systems. I would skip the chanel 3 conversion and go straight
modulator to UHF if I were you unless you have a need for the ch. 3 signal.

A modulator which tunes the entire band does add to the cost. You can
get commercial units that tune all channels if thats a necessity.

I was just thinking...remember the "Rabbit" system that was popular
about a decade ago? It was used for transmitting a signal from your VCR
or sat rcvr to other sets in the house. I can't recall if it used UHF
or some proprietary frequency. That might be worth looking into.

GL,
Bill

Not in the States. VCR modulators here output on VHF channels 3 or 4.
(60-66 or 66-72MHz)

If the OP can find a foreign UHF modulator, it should work with US
signals, with two possible issues:

- The sound-video separation is different. This means the sound will be
on the wrong frequency for an American TV. If the OP doesn't care about
sound then this isn't a problem!

- TV channel frequencies are different in different countries. Most
Australian channels don't coincide with American channels. (if a
modulator tunes Australian channels 30-37, the only channel in that
range that corresponds to an American channel is 32, which is American
channel 28)

Are European/Australian VCR modulators continuously tunable? Or can
they only be set to discrete channels?

http://www.73.com/a/0019.shtml offers a "block converter". (among
dozens of other items! It's about 3/4 down the page on the left-hand
side, stock #AE047) It's a broadband frequency converter that will
convert a US channel 3 RF signal up to US channel 37.

Hi Doug,
thats interesting - us in OZ had the same VHF output system years ago,
but when we got UHF broadcasting, all the VCR's went to UHF output.
Most (if not all) are tunable over a narrow range,(via a trimmer cap on
the rear panel) some of the more exotic ones (even from dumpster
diving) have user settable(sp) output with the actual RF frequency on
screen - makes a crude UHF sig gen.

The advantage of the UHF output over the older VHF only is no
co-channel QRM from the strong Ch3 signal to local on air channels.
Agree with the different standards - nowadays, this is not an issue as

even the el cheapo VCR's are multi-standard. Saves having to manufacture for different markets, and the new chipsets for this are dirt cheap. Most new ones have an integrated tuner/if/video conversion "can" - unfortunately, bus controlled so difficult to experiment with unless you are comfortable with microprocessors. I aint - firmly rooted in the analog domain!

UHF in the States long predates the VCR. But that may be why we stuck with VHF output -- because early UHF tuners were pretty bad and many Americans had experience with their poor stability and difficult tuning.

So the VCRs with on-screen frequency setting are also continuously variable? I mean, you can select a RF frequency that doesn't correspond to a valid Australian channel?

> The advantage of the UHF output over the older VHF only is no
> co-channel QRM from the strong Ch3 signal to local on air channels.

True. (though with the dawn of digital TV in the States I'm not so sure that's enough anymore! Here in the Nashville area we have stations on channels 20, 21, 23, 24, 26, 27, 28, and 30 among many others...)

Cable TV boxes use the same modulators as VCRs. CBS-TV had a serious problem when they began digital broadcasts in Chicago a few years ago. They'd been assigned channel 3 for their digital transmitter, and it clobbered the cable boxes. Of course, QRM on the boxes' output channel meant that it clobbered *every* channel on the cable!

Multistandard equipment is more common in the US than it used to be, but it's still pretty rare. I only know of two variants of NTSC - the one used in Japan, and the one used in all other NTSC countries including the US - and they vary only in the RF carrier frequencies used. (even sound-vision separation is the same) Still, American equipment cannot (usually) be switched to receive Japanese frequencies.

Yeah, my microcontroller experience is pretty limited as well!

For the most part, USA VCRs or cable boxes have always had a switch for ch 3/4, or to a lesser extent, 2/3. The way the channel allocations are done in the US you won't find adjacent channels broadcasting in a given area so one or the other is supposed to work. Guys halfway between Philadelphia and New York City will of course explain why thats not always workable.
Nowadays they have dropped in the digital channels, yes in VHF too, with no need to regard adjacent channels which turns the cake upside down. Given the capabilities of modern tuners it makes much more sense to have selectable UHF channel outputs on consumer gear. There's still some free slots in the most crowded metro areas...although the "digital data" people are lobbying hard to get access to those unused frequencies.

Hmmm, lets see. You spam newsgroups with "coming soon" auctions, then
with current auctions and then with "one day more" notices.
Why don't you make a list for maybe one month and just post it once?
Some of us get really pissed off about the constant reminders to "come
look at my stuff".
Just when did you decide that public discussion groups were your
personal corkboard for selling?

I'm not carping about posting ebay links - I'm carping about the manner
in which you're doing it as if I need 3 whacks across the head to look
at your stuff. Once is enough.

Hi Bill,
digital here has been a mixed bag - where I am, its line of sight to
the hills which is full of UHF translators - thats not so bad for
analog, as you can "see" the QRM underneath the ch you have chosen as a
RF out. Digital, well, you dont get nothing on screen, so it looks like
the front end of the VCR has died. Took me a while to twig to that one
- even the local agents for a very well known brand didnt know it and
were trying to sell me a new front end to fix the problem!

Hitachi have had OSD of RF frequency out for a while now - Philips also
in some of their tv;s, and TEAC as well, so it will pretty well be
universal before long. The Chinese are really gearing up - they do make

some pretty sophisticated gear, but will happily sell us rubbish if we want it as well!

We also have a FM broadcast channel on the same tower as the VHF transmitters - it QRM's TV ch 10 depending on how good the tuner front end is. - Funnily enough, (well, it isnt really, more obvious) the older style rotary UHF tuners with ganged RF and LO tuning dont seem to have any trouble, only the varactor tuned ones. But then, they are the sweepings of the factory floors of Asia - bought on price rather than performance. Try telling the customer this tho....

Usually the primary, or one of the primaries, begins at pin 1. If you get two windings that measure about the same resistance, and its a few ohms, it's probably a split primary. You can insure that you get the phasing right if you connect the two windings in series, and apply 120V to just one of the two. Then if you get about zero volts across the whole series connection, you have the two connected counter-phase, like dotted ends connected together. Try the other polarity for one winding and see if you get 2* the applied voltage across the whole series connected primary, which would be in phase (dotted end of one to the undotted end of the other.

It's helpful if you have a variac (NOT a lamp-dimmer triac) so you can run the voltage up slowly. An alternative that works nicely is an incandescent light bulb in series with the 120V supply. If the series lamp, 100 watts or so, lights very dimly or not visibly at all, with nearly all the voltage across the transformer winding, you've almost certainly got it connected to the primary. The light bulb will keep you from blowing breakers or fuses. If the transformer has an internal short or you're hooked to the secondary (or if you short the secondary or put a heavy load on it), the lamp will light much more brightly.

Of course, be careful. The primary side can give painful shocks, possibly leathal ones. And the secondary side can deliver enough current to make pieces of metal very hot.

Cheers,
Tom

Additional thought: you may be able to see wires connected to the terminals. If so, it should be obvious which windings are the higher current ones and which are the higher voltage ones.

It's also possible to make estimates of the current rating of the windings from the wire size.

Cheers,
Tom

The Keyword here is how 'bad' the tuner front end is :) Its probably a tossup if there's a harmonic being received instead of a mixing beat but at least tunable sets have a chance of getting away from it.

Here in the US, gear usually has options of off-air, cable, cable HRC (harmonically related channels) or cable IRC (incrementally related channels) . Depending on the freq of the FM station *sometimes* you can force the set away from the FM harmonic by selecting one of the oddballs. But if its beating with the video there's no cure.

Do you still have folks with rotary tuner sets down there? I haven't seen one in a customer's home for 30 years on this side!

==========

To check the windings of any transformer I always use another mains transformer with a low secondary winding output of say 12 or 6 volts. I connect the low voltage output to one of the windings of the 'mystery' transformer and with a DVM check the voltages on the other windings .This provides the winding ratios ,from which the actual operating voltages can be derived ,with additional information from winding resistances.

To check the current ratings of a secondary winding I increase the load on that winding until the output voltage is 95% of the 'no load' voltage . The corresponding current is the safe maximum current to flow through the winding .
Depending on the transformer's output voltage ,I use car bulbs or a lenght of fencing wire (iron) in a bucket with water for low voltages , light bulbs (parallel and/or in series) for voltages up to 500 V or even higher (be careful).

Hi Bill, nope, not many left with rotary tuners (on UHF) - but I still
get called in to fix them occassionally, and even more so that some of
them still have good tubes in them!

Hello All

I am building a LF/MW/HF Preselector and I would like to use my computer to layout a pattern, 4 inches (101.6mm) by 10 inches (254mm) using 2 variable capacitors, three rotary switches, two potentiometers and some toggle switches. Toggle switches are no problem but the other controls should be "calibrated" type of layouts. I have used MS Paint with only letters and numbers, reversed and applied to a clear transparency with a laser printer. This worked ok but to draw lines at an angle do not work. If I have a layout I can copy or scan I believe that would work ok. I have done ok with schematics.
I have some Dataq dry transfers but some are too small or too large. I tried scanning and resizing but I cannot get rid of the "blue" background.

I have some graphics programs but the learning curve is steep and I am not an artist so I do not understand much of the terminology such as "layers" etc.

Any suggestions would be appreciated. If you send a link, please make sure it is "direct" and not to a site where I have to figure out what you meant to tell me.

Thank you in advance.
Please answer to the group as this address is only for logging into Google Groups.

Richard

One pitfall not already mentioned is that simply combining the R-G-B and sync signals coming out of a VGA card won't produce a US standard NTSC signal. A US television signal (NTSC compatible) uses a 15.750 kHz horizontal sweep rate. The lowest VGA resolution (640 X 480) uses a 31.5 kHz sweep. Higher resolutions use higher sweep rates. This scan rate incompatibility may complicate your project. Of course, there are some specialty video cards around that have an NTSC video output, in addition to VGA. Those cards have an on-board scan converter.

Good luck,

Roger K6XQ

2884. 12VAC to 24VAC Transformer -- Ideas?

I need to find a transformer (converter?) that will allow me to upconvert from 12VAC to 24VAC in order to drive a small motorized device (50 watts) for continuous duty. I tried using a 110V/220V 'travel' transformer -- it gave me the correct voltage but not enough output wattage (probably not enough turns on the windings). I need a transformer rather than an electronic converter since I am driving an AC motor... isolation isn't an issue so I could go with an Autotransformer. Thanks.

A simple transformer with two 12 windings would do the trick.
The primary windig will give you line voltage as an extra bonus.

Radio Shack has 115volt to 24 volt transformers But if you need to go from
12 to 24 you might look for a transformer with a 12 and 24 volt winding.
Feed your 12 volts to the 12 volt side of the transformer and use the 24.
Make sure you insulate the 115 volt leads as they will be hot.
If you cant find one go to Radio Shack and get a 12 and 24 volt transformer,
connect the 115 volt windings to each other, feed 12 volts in and and get 24
out.

Roger,

Wouldn't this be be exactly double of NTSC, in which case the TV would see every other frame of the composited VGA? Or, because I am intending to run the card in Linux, could I create a resolution below 640X480? But you may be right, a surplus video card with S-video out would sidestep this problem.

I am thinking of building up a single ended 4-400A for six. Mainly cuz I've got a old homebrew HF amp with a good bit of the "stuff" I need to do it with.

I wonder (since I'm a bit rusty these days), if I can Grid Drive it? I will only have a basic transverter output (8Watts) available.

Anyone point me to a site or material about the input and output circuitry needed?

Any thoughts?

Dan/W4NTI

If you run the tube in class AB1 it won't need ANY driving power, just
voltage. So with the right input network your 8w exciter should do the
job. You WILL need to neutralize the 4-400A at 6 meters. At this
frequency the tube is below it's self neutralization frequency, so
a conventional neutralization network will work. (above the self
neutralization frequency you have to resort to tricks such as series
tuning of the screen leads).

There was an QST article some years back using a 3-500z on 6 meters.
The tank circuit used a copper tubing coil with a rotating shorted turn
for tuning instead of a variable capacitor. However a Pi network can
work on 6, though you might have to use a 'dual disk' capacitor and
tap the tuning cap down on the tank coil.

BTW the 4-400 is good for use up to about 110mhz.

Try an electrical supply house and look for a 110/220 or 220/440 of
appropriate power rating. They are used for various industrial
control needs as well as power conversion off 1 phase of 3 phase
feeds. All you want is the turns ratio with enough iron and copper to
handle the wattage.

> see every other frame of the composited VGA?

If the TV would ignore the sync pulses that arrived too soon, you might get two images, side by side. But that ignores the other complications that I didn't mention: VGA and NTSC don't use the same vertical sweep frequency. And NTSC is an interlaced vertical scan, meaning you get alternating lines of display, rather than a complete image scanned top down. NTSC requires two complete top down scans to get all lines of an image. VGA is non-interlaced.

>Or, because I am intending to run the card in Linux, could I create a resolution below
> 640X480? But you may be right, a surplus video card with S-video out would sidestep this problem.

The video card has more to do with the VGA scan rates than the operating system. You often see crystal controlled oscillators on video cards so you are locked into what the card manufacturer provides. I can't rule out some flexibility here, but I think a video card with NTSC video output would be the surest way to get this idea to work.

Roger

The 110/220 transformer had more than enough turns, they were just
wound with wire that was too small for the current that you require.

You could try to find a similar 110/220 transformer with more current
capacity, but this would be big.

An alternative would be to pick up a transformer with 2 12V
secondaries. Ignore the primaries and put the secondaries in series.
Then you apply your 12V between one end and the "center tap" and you
get 24V between the 2 ends, assuming you have the phasing right.

The 2 12V secondaries have to be rated for the current you plan to
draw.

Yet another possibility is to get a 110-to-12 volt transformer and a 110-to-24 volt transformer. Connect the 110 volt windings to each other, put your 12 volts into the 12 volt winding and take 24 out of the 24 volt winding. I'm sure you're getting the general idea. . .

This coming Sunday....

+++ Now even more Buyers Parking !!!
Thanks to TKT we have use of their new parking lot
across Albany St from the SWAPFEST !!!

!! ** More Buyers PARKING is available ** for details see
http://web.mit.edu/w1gsl/Public/flyer

*** !!!! In our Traditional GARAGE and the adjacent lot !!!! ****
so come rain or shine or super heat the Flea is on !!!

********* $1 buyers discount with hardcopy of this notice ********

COMPUTERS - ELECTRONICS - HAM RADIO - COMPUTERS - ELECTRONICS - HAM RADIO

FLEA all SUMMER at MIT
Sunday June 19th 2005
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take
place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >2000 cars!

Buyers admission is $5 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $20 for the first and
$15 for each additional at the gate.

The flea will be held at the corner of Albany and
Main streets in Cambridge; right in the Kendall
Square area from 9AM to 2PM, with sellers set-up
time starting at 7AM.

SEASON PASS + Advance Seller Discount

A sellers discount season pass is available which
offers a 30% discount. By prepaying you get a
discount and earlier admission. See the registration form.

*** Attention Sellers ***
Prepaid vendors.. Season Pass or monthly,

will be admitted FIRST.
Separate lines will form prior to gate opening
for prepaid and nonprepaid vendors

!! RAIN or SHINE !! Have no fear of rain, a covered
well illuminated tailgate area is available for all
sellers (6'8" clearance).

Talk-in: 145.23- (PL 88.5) W1BOS/R and
W1XM/R-449.725/444.725 (PL 114.8/2A).

Sponsors: MIT Electronics Research Society
MIT UHF Repeater Association (W1XM)
MIT Radio Society (W1MX)
Harvard Wireless Club (W1AF)

For more info / advanced reservations 617 253 3776

********** $1 buyers discount with hard copy of this notice ***********

<<<<<<<<<<<<<<<<<<<<<< cut here >>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>

Mail the coupon below by the 5th of the month to be a Prepaid Vendor.

FLEA at MIT 2005 Rates

SELLERS

To use your prepaid spaces the named vendor MUST be present.
Rates include one admission per space.

Advance $17 First space - includes $10 Cambridge Vendor License
$12 Additional Spaces
Must be received by the 5th of the month.

Gate Admission $20 First Space - includes $10 Cambridge Vendor License
$15 Additional Spaces
Admission is after the prepaid vendors

Early Bird Buyer -Admission after the prepaid vendor line is admitted. ~ 7:15AM
** You may not sell. **
$15 per person at the gate.

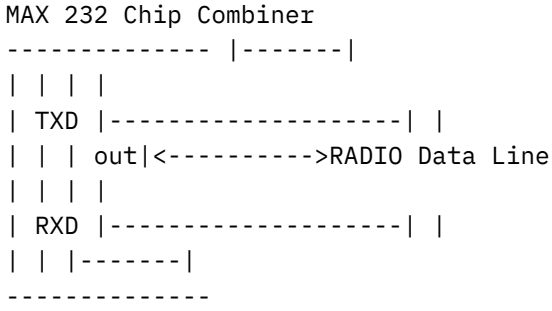
2899. Programming a Kenwood TK-690 VHF Transceiver

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-06-15 12:52:36 UTC
From: pinpassion <mjdrum@comcast.net>
Message-ID: <1118839956.456599.133870@o13g2000cwo.googlegroups.com>
Source record: 18532

Hi Gang,

I am trying to work a circuit that I can use to
program a VHF receiver. I'm going to use the Maxim
MAX232 IC to do the TTL to RS-232 voltage conversion,
and this is very common. The trick I have to accomplish
is to take the TXD and RXD (transmitted data/received data)
on the TTL side of the chip, and combine it into 1 line
going to the radio.



Most interfaces are full duplex and they don't split up
the TXD and RXD signals. On this particular Kenwood radio,
they do. There is still data beng sent to the radio, and
data received from the radio. It is just using one line as
the pipe for both data lines. I was thinking two transistors
and a blocking diode. Anybody have any ideas? Kenwood sells
a cable that does this, but it's expensive and I am trying to
find a homebrew solution. All I need is the combiner circuit.
I already have the schematic for the MAX 232 circuit. This is
5 volts TTL. The radio is a Kenwood TK-690H.

Thanks in advance for any help.

Mike

Source record: 18534

I'm assuming you have no control line on your side to set the dataflow direction, but that the radio enables its transmitter when required, and sets it to HiZ when receiving. It's possible that some obscure control character(s) or other RS232 line sets data direction, but let's assume the arrangement is simple (does your manual say anything about this?).

Simply tying the RXD line directly to the radio data line, and the TXD line to that with a 3K or so resistor ought to work. Anything you send will be echoed on your RXD line if you use this scheme, but under our simplicity assumption it is likely the Kenwood cable does this as well.

Note that I'm assuming RXD is the input to the MAX 232 and TXD is the output. RS232 nomenclature is ambiguous.

Regards,
Glenn Dixon AC7ZN

Oopsie, didn't read your post carefully enough--the radio uses TTL
levels so the MAX 232 is near the radio? I assumed the data line was
RS232 levels (dumb me--you said TTL twice). Lets see....well something
around 3K may still work, though the data line would have to be
short...

Source record: 18536

This is not answer to the question but another way of achievieving the result:

I am assuming that the Kenwood I/F is similar to the Icom. Icom is also selling a quite expensive I/F. I did not want to buy the I/F and I was not in the build-my-own mood either.

My solution: I used a USB to serial converter and removed the level converter (it was not a MAX232). One of the Belkin USB-to-serial adapter I already had is bulky enough to allow me to do the surgery very easily. The plastic shell opens w/o problems. Since they are many uses for a serial adapter w/ "TTL" levels, I wired the input of the level converter to the 9-PIN connector.

This adapter is used to configure an IC706 MKII. My laptop has no serial line so I had to use a USB converter anyway. The cable from the DB9 to the IC706 combines RX and TX as described earlier.

Good luck.

Motorola/Freescale has several ICs designed for video modulators that
use PLL tuning. One of them may do just what you want, rather than
building an upconverter.

<snippety>

Are you 100% certain that this particular radio even uses TTL levels on the programming side?

I say this only because I work with TK-790's frequently, through my day job, and they do not require any sort of RS232 to TTL conversion. They're programmed through a custom cable
straight from the computer's serial port to the microphone connector.

Perhaps you should dig into the 690's service manual before expending much effort?

Happy hunting.

Hi,

Thanks everybody for the help and suggestions.

I have heard through other users of the Kenwood 90 series radios that the factory cable has the MAX232 chip within one of the connectors, as well as a data combiner circuit that sends/receives information over 1 data line through the radios microphone connector. The radio deals with 5 volt TTL signals and not the 12 volt rs-232 voltages. If you open your factory cable, you will probably see these circuits and can verify what I have heard.

> The Eternal Squire

I wouldn't buy the evaluation board either. THere is a good chance
of finding the chip in some junk electronics with a module you can adapt
to your needs. Even if something only offers a ch 3 or 4 output doesn't
man it can't have the newer PLL modulator chip. Most equipment has a
microprocessor and supports the serial buss to talk to the chip so it
can be programmed for different markets.

I routinely soldered 244 pin packages under a stereo microscope, but
my vision has been poor since I was a kid.

It is called a nibbling tool. You start with an undersized drilled
hole, and this tool nips away at the edges until you have what you
want. Slow, but versatile. Under $20 for a basic one.

A rotary tool like a Dremel, or one of the larger spiral saws, could
do this as well.

If you need to do many holes of the same size, and need precision,
look into Greenlee punches.

Happy trails,
Gary (net.yogi.bear)

The TUBE won't require any driving power as it won't draw any
grid current. HOWEVER there WILL be losses in the input coupling
network so some power will be required to generate the required
driving voltage. My point was that 8 watts should be enough.

I did that, but with identical transformers to replace a small
power transformer giving 115v@20ma and 6.3v@.6 amp
Used two 6.3v 1A transformers back to back and a bridge
rectifier on the 115v side.

If neatness really counts, you might want to just drill four corner holes and use a coping or jig saw to cut from hole to hole. A bit of filing at the corners and where the saw strayed from the line should produce precision results.

The Adel Nibbler is good, but I find it hard to nibble to a line, and it requires a minimum 29/64" hole to start. It is also limited in the thickness of material it will work with.

A rotozip type bit in a dremel will 'rout' out the required hole
You can buy a router base for the dremel tool to make the job
easier. You can make a frame with a square cutout to guide the
router base to make the exact size hole you need. Norm Abram does
this (with wood) on the New Yankee Workshop.

Nothing special. (You can use an octal tube socket for
the same purpose, cheaper!)

I have some weird double FT-243 crystals though.
Made for Uncle Sam, they house two crystals in one unit,
either a dual channel job, or one for the transmitter and
one for the receiver on the same channel.

Another useful thing is the "abrafile" or rodsaw - a round diamond
dust coated rod that fits in a hacksaw frame. Whichever way you do it,
its always a bugger of a job to get nice and neat! But after about 20
years, it does get easier. (or you get less fussy, anyway)

2925. Need schematic / documentation on 2 Heath items

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-06-20 23:47:43 UTC
From: lennyw@comcast.net
Message-ID: <1119311263.845560.42970@z14g2000cwz.googlegroups.com>
Source record: 18457

I've got 2 hot hamfest finds so far this season and need documentation
both of them. If you have leads on schematics or mauals, I'd ppreciate
hearing from you.

Here are the items:

1. A Heath HA-201A 2 meter fm amplifier. A schematic would allow me to
figure out how to re-bias this amp for linear service. Please note that
this is quite different from the HA-201 (without the "A" suffix) for
which there IS documentation at the BAMA site.

3. A Heath IB-1102 nixie based frequency counter. It's currently in
working condition but it triggers poorly at high frequencies. A
schematic / manual would allwo me to re-adjust it / modify it for more
reiable opearation at > 100 MHz.
A kind member of rec.radio.amateur.eqipment was able to get me a
schematic for the similar IB-1101, and it will help some, but one for
the IB-1102 would help more !

The commercial sources for documentation on these 2 items are
asking very high (way more than the cost of the items themselves)
prices for the paper work.

Thanks in advance for any leads.

73,
Lenny W2BVH

As of 15 years ago you could still call up Heath/Zenith and get manuals
for much of the old equipment -- I was astounded when it worked for me.
I have absolutely no idea if they still support the old stuff, but
there's nothing they can do to you over the phone that makes it not
worth a call (unless you know for a fact they don't support the old
heathkit stuff any more).

Thanks for the suggestion. I called Zenith (now LG Electronics) twice.
First to talk to "customer service" who never heard of Heathkit and
said they don't carry manuals. She had some trouble formulating a
complete English sentence, so I didn't trust her reply.
My second call was to "parts". After 15 minutes on hold, I decided it
wasn't worth any more time, given the (un) likelihood of a positive
response.
Well, I guess I'll try one more rec.radio.amateur subgroup and see what
happens. Hope springs eternal :-)

Welcome to the boatanchor world, for old computers it is even worse, documentation was rarely taken care of as well as radio docs. For my old computer collection, I regularly expect to pay more for docs than the computer.

Even setting up archives of this sort of material doesn't work past the death of the collector. The cp/m computer world lost the person who was collecting boot disks for all machines and now can't seem to get the disks back.
thanks, John.

==========
And even in the same place.
From the training kit on offer I recognise a similar design as the ET-3300
Laboratory Breadboard , I bought in kit form in the mid 1970s ,which I still
use on a regular basis.
Heathkit is definitely not dead,be it they now supply somewhat different
products,to suit today's world.....good to see that !

2934. FA:Mcurdo Silver 5C,Extremely rare.later today

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-06-22 14:01:19 UTC
From: Heytubeguy <heytubeguy@worldnet.att.net>
Message-ID: <Paeue.1005915$w62.631269@bgtnsc05-news.ops.worldnet.att.net>
Source record: 18467
Cross-posted to: rec.radio.amateur.boatanchors,rec.radio.amateur.equipment,rec.radio.amateur.homebrew

1932/33 McMurdo Silver 5C to be listed later (~9-9:30 PM CDT) today:
Extremely RARE and in working condition, a very nice McMurdo Silver 5C,
Super het of 1932/33 that was featured at the Science Exhibit at Chicago
Worlds Fair. BE ADVISED: if you are looking for a receiver that out performs
the likes of R-2000, HQ-180, etc, pse do not bid-have a nice day. This radio
is for the serious collector that appreciates such a exceptionally rare
antique. I copied SSB on 20 m and 70m this AM BUT I had only an attic
antenna so signals were not as strong as they should be. Covers 1.7-4, 5-12,
& 9-22 mhz. Mid-band is the 'hottest and 10 Mhz WWV is basically right on. I
received noise on 1.7-4 (ant?) but it is receiving a 4 Mhz sig generator
output quite well. Sensitivity drops on the higher band but receives AM
broadcast stations in the 18-9 Mhz region. Unpacked weight is 28 lbs and ~
34 lbs with the 11" speaker! I highly recommend professional packing, but I
will ship in a very large box for protection. FULL INSURANCE IS REQUIRED--NO
EXCEPTIONS. This unit is NOT MINT (which means NEW to me) and if I were to
keep it I would continue to make a few more corrections. It IS very clean.
All tubes check way beyond minimum. All shields in place though may not be
original. Front is crisp and clearly printed (repainted?). SPEAKER INCLUDED;
no cabinet however.Sounds great.

There at least two (ham) places on line that sell old manuals (copies).
Several places on line with free download. I ordered a Heath tube checker
manual from one - don't remember which, but it was a ham.

Here are my bookmarks (all work today):
http://www.sarrio.com/sarrio/products.html
Go down to "Vintage Manuals for radios and test equipment:"
He shows Both of these
Heathkit (C) HA-201A Amplifier $20
...
Heathkit (C) IB-1102 Freq Counter $32

HEATHKIT KEY
C = COMPLETE MANUAL (EVERYTHING)
F = (F) (Photo, Specs., Schematic)
P = PARTIAL MANUAL (No construction detail)

http://www.btinternet.com/~geoffrey.brown3/manuals/

http://bama.sbc.edu/free.htm
(Looks like you know about this one)

Do a Google on "manuals Ham radio vintage" and you'll get many hits.

2937. Looking for 12V tube Rx project info

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-06-22 18:56:26 UTC
From: Ed <Huckleberr_REMOVE_@bigvalley.net>
Message-ID: <Xns967D79AD24D7spectrumhogstarbandn@207.106.92.175>
Source record: 18470

I am looking for a nice schematic, and perhaps additional info, on a 12V (fil. & plate) tube superhet Rx; just something fairly simple for CW/SSB reception without bells and whistles, and preferably for 75M/40M reception.

Can anyone point me to info on this? Thanks.

Ed K7AAT

2938. YIG filters (and oscillators): How do they work?

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-06-22 19:10:10 UTC
From: Joel Kolstad <JKolstad71HatesSpam@yahoo.com>
Message-ID: <11bji34rmd33q8d@corp.supernews.com>
Source record: 18471

Just curious... how do tuneable filters, oscillators, phase shifters, etc. made from Yttrium Iron Garnet (YIG) materials work? Does an applied DC magnetic field alter the effective permeability of the material? Or is something more complex going on?

Also... what tends to limit YIG devices to not typically be used much below some "many hundreds" MHz? Is it just loss in the material starts to become prohibitive? Or something else?

I've done a little Googling, and although there's a lot about YIGs out there, it's usually at either a much lower level or much higher level than what I'm after here!

Thanks,
---Joel Kolstad

2939. Looking for John Roy Worthington EP2RW/GW3PNZ

Newsgroup: rec.radio.amateur.homebrew

I had a professor in a laser electronics class make an offhand comment
on how the ground energy state of ruby (ruby = YIG, here) lasers
seperates into a number of seperate states under bias, and this can be
used to make a microwave oscillator. Translated, that means that the
electrons in the material are what's actually resonating. I suspect
that this is the effect that's used for YIG oscillators.

As for the rest of the whys and wherefores -- I just don't know.

Source record: 18478

I was curious about that recently, and _somewhere_ I found a really nice explanation. Wish I could point you to it; I won't do it justice. But the basic idea is that magnetic dipoles (from the electrons in material) align with the DC magnetic field. If something perturbs them, they will oscillate with a natural frequency depending on their mass and the strength of the restoring force: the externally applied field. Think of a (tiny) bar magnet on a pivot, like a compass needle. If there is no damping, it will oscillate. The strength of the externally applied field determines the restoring force, and therefore the oscillation frequency. The reason given for making the YIG resonator a ball is to get a very uniform magnetic field through the whole ball so that all the atomic dipoles have as nearly as possible the same resonant frequency. The high Q resonance, of course, is what lets it be a filter or the tuning element of an oscillator. It's very handy that it's relatively easy to tune over an octave or more range. However, since the tuning involves changing a fairly large magnetic field, it's much slower than tuning with a varicap diode.

OK, now that I've written all that, of course it becomes easy to find the reference: http://pw1.netcom.com/~dstraigh/yig.html Oh, well.

Cheers,
Tom

Source record: 18479

About the freq limit: consider that the resonant freq depends on the applied magnetic field, and you can't perfectly shield the osc from ext fields: power line frequency things, Earth's field, etc. Since f is linearly proportional to the field strength, things are percentage-wise more immune to external fields if the field strength is high, and thus the resonant frequency is high. Also, other designs are relatively more practical at lower frequencies; it's no great trick to make a lumped LC oscillator at a couple hundred MHz (though electronic tuning over an octave range becomes a bit of a chore because of all the stray capacitance). So it's a matter of the frequency range over which they are relatively more practical and economical than the alternatives. And of course, there are many factors to the "practical" part of that.

Cheers,
Tom

Thanks, Tim, that helps a lot! For what you've said, if I were to apply a mass-spring analogy, the electrons would end up as the mass and the DC field strength would correspond to the spring constant.

I'll read up at the link you provided. It would appear that with no DC field applied, you'd get the lowest resonant frequency... at until not too long ago, that appeared to be in the ballpark of 1GHz. Now it's not uncommon to see 500MHz YIG filters... I wonder what changed?

The application I had in the back of my mind was for nice, sharp filters in the high VHF/low UHF range. I saw a circulator recently for 432MHz and, while it was large at about 4" square (but flat -- only about 1/4" thick), it still struck me as a pretty nice alternative to trying to build a transformer-based isolator at such frequencies. Hence the thought of perhaps being able to use YIG filters down there as well...

I'm building a few yagis for 432 and two meters and need a source for stainless steel push on retainer rings, sometimes called push nuts (incorrectly) to fit element diameter of 3/16" aluminum rod. I know they are made but cannot find a source searching with Google. Any help here would be appreciated. I have the spring steel variety but they rust after 2 or 3 years so the antennas have to be taken down and the retainers replaced.

Thanks and 73,
Ken, KC4IH

They use the spin of the electrons. If you apply a magnetic field to the YIG,the spinning electrons precess at a rate proportional to the magnetic field. This rate happens to fall in the microwave region and a typical range is from 8GHz to 18GHz.
The sphere is coupled to the oscillator circuitry by various means - a loop of wire for example - and the spinning electrons look like a resonator to the circuitry.

That design was common in the car radios of the late '50s to early '60s. They used tubes for all functions except the output amplifier, which was a transistor. You can probably find old Sams manuals on ebay, or just copy an existing HV schematic and substitute the 12v tubes. There isn't a very great difference.

Incidentally, if you have trouble finding the tubes designed for 12v on the plate, ordinary HV tubes worked fairly well but with somewhat lower gain. My first job after high school was repairing those radios.

Also, the 12v tubes were quite prone to develop microphonic problems. The design only lasted a few years until good transistors became available cheap. They are an interesting bit of electronic history, but not really practical today. A five cent transistor will outperform what has become a very scarce and expensive 12v tube.

But have fun anyway. :-)

Operating tube plates down to 12 VDC supply is pushing things a
bit far, to be honest with you.

Setchell-Carlson managed to do it with loctal-base tubes running
off of a 24/28 VDC aircraft bus back in WW2 times. No dynamotor,
just that cute little box referred to as a "range receiver" or
BC-1206.

I bought a couple of them many years ago, surplus, principally
to get the nice compact 3-gang variable capacitor. Fired one
up in the company lab at 26 VDC and it was still in-spec although
those specs weren't the best. At 24 VDC the spec rating was
marginal. At 22 VDC it was below spec...but then the filaments
were also running cooler at 11 V each.

Don't remember what the IF (135 KHz) BW was, but, running with
a crystal-controlled converter ahead of it, the 195 to 500 KHz
tuning range could cover 75 or 40 meters no problem. A thought.

Not exactly.

On HF, it is fairly unusual that you can hear both sides of a conversation, unlike VHF where if I can hear one station, I can usually hear the other. So when I want to call someone, I listen first. Hearing nothing, I send QRL? (or on phone, "is this frequency in use"). If the station I can't hear gets my QRL, he sends C and I go off looking for another frequency.

Very few, if any, digis actually listen first. Even if they did, they don't have a way to say "Is this frequency in use" and understand the response. And even if they could, they really don't have the opportunity to change frequency, since they need to call on the frequency that the remote robot is listening. It seems as if it would be very difficult to make these automated stations be friendly to other users.

That being said, it looks as if Winlink 2000 is going to be come a significant part of our emergency response, which is one of the reasons we have access to these frequencies to begin with. We should be looking at reasonable solutions, perhaps developing new technologies to enable this sort of capability, rather than just flaming.

Both the pro and con in this argument are absolutely unwilling to listen to/believe the other side. We amateurs need to get our act together and figure out how we can expand the use of a technology like Winlink 2000 without making these automated systems even more of a nuisance than they already are.

There's plenty of space. We just don't manage it worth a darn.
If you listen to the ham bands, you'll find that the
vast majority of our allocation is wasted. For instance:
you could put every CW QSO during Sweepstakes into about 75 KC of
spectrum and have lots of elbow room.
For phone, probably 100-125 KCs would be a big plenty.
People want their freqs to end in "5" or "0" and that
is just poor spectrum management. Look at ten and six
meters, even at the peak of the sunspot cycle;
90% of it is empty, wasted space.
Every major city has 100+ repeater pairs allocated,
twenty or thirty repeaters on the air and maybe *three*
that get any sustained use.
That's pitiful and a matter of *ego,* not communication.
75 meters is "crowded" only because of our 5-n-10 KC mindset.
Our problem is ego and "we've always done it this way,"
not a lack of spectrum.

We're going to either make room for new and enhanced
modes or we're going to be swept aside like blacksmiths
and locomotive boiler makers, guys.
The times is passin' us by....

Well.... first things first, of course.. why are we always posting such discussion in all these groups for commerce?

Second, and I quote.... "Whatchu talkin' 'bout Willis?"
> If the station I can't hear gets my QRL, he sends C and I go off looking
> for another frequency.
<sorry to whoever posted that. :-) >

I would normally bypass these things but I've been thinking about getting another HF rig lately....and I've been considering why I keep selling them off, trying to warrant a purchase again. I'm thinking it has to do with the words "purpose" and "use".

So, I'm looking at getting back into it and doing something besides setting up a radio and just randomly playing with it or gluing the vfo on some nonsense gathering place.

So here are my questions and observations for your perusal and general flaming.

From the original link posted:

That the HISTORICALLY HIGH LEVEL OF INTERFERENCE BY PACTOR STATIONS to everyone else has demonstrated time and time again that even the operator-controlled Winlink Pactor stations don't care if a frequency is busy (because they can easily take it away), in their passion to get their email from the Internet, so they MUST NOT BE ALLOWED to mix with hams trying to COMMUNICATE WITH EACH OTHER!

Q: Someone please take a minute and point out a single coherent thought or plausible point in the above statement. Bearing in mind that tuning to any random freq can find people squawking over each other like the noise in a crowded room, or a CW freq sounding like my kid running down the "try me" aisle in the toy dept... When did it become impossible for my station to hear 2 other stations that can't hear each other?

Next, from the original link posted.

That ham radio is a HOBBY, not a quasi-commercial email "service" as Winlink provides, and that ham radio, from the very beginning, has always been mainly about hams communicating with other hams, and not about being used for unattended email gateways to the Internet, mostly for a few sailors, because the FCC Maritime Radio Frequencies were set aside for that purpose and are underused.

Observation: If it serves a legitimate purpose and assists a single sailor, military or civilian, it serves a greater purpose than your latest blathering, contest, or quasi-award. The author can 'pucker up and plant one' on that statement. Again, if it is a ham station to ham station, WHERE is the plausible point?? ..... I think I hear a tiny voice yelling "ME, ME, ME... I shall rule the world!"

Also from the original like posted:

That all unattended wideband digital operations, of any type, MUST be confined to the current sub-bands for automatically controlled digital stations, and not allowed to use any frequency they wish just in order to avoid having to wait a short time for a clear frequency in the sub-bands.

Observation: I think SHOULD is a better word. Also take the entire point and reverse it, maybe they feel the same way in a crowded band. Why can't YOU wait a short time for a clear frequency?? [I shall rule the world!!] Also, if you [and Winlink, and Amateur radio in general] wake up and smell the ALE, then you again have a moot point.
If you've ever been on a radio, you realize that attended or unattended matters not; due to world dominators. The problem you're having is with courtesy, not digital ops. Good luck freeing the world of jerks and morons. [and from experience, a dense population infiltration such as the one in ham radio would be a good place to point yer scattergun when you start.]
There's lots of people with lots of free time to build up their personal anger levels for whatever reason, then look for a [safe] place to vent frustrations.
It's the same with the www.
Also, if you paid any attention to Riley at any point, you'd know that he already said APCO25 is fair game on the phone bands, so you are actually showing up on Saturday for the Friday night fights. Sorry you missed us, but thanks for coming out.

And again from the link.....

To stop this attempted takeover, *[I WILL START MY OWN]*
EVERYONE ELSE needs to vote NOT to agree to the Winlink request, so ARRL does not get the wrong impression that the "majority" of hams want to sacrifice the frequencies they use for communicating, so that the less-than-1%, that are Winlink users, don't have to wait longer than 90 seconds to receive an email on HF or can't send picture attachments to the Internet.

Q: STILL trying to understand why he keeps saying "stop hams from communicating so that hams can communicate!" and "I'm not gonna wait 90 seconds on a bunch just because they can't wait 90 seconds!"
You know what... I think Winlink has something wrong....maybe... there're WITCHES!! Everyone chant and point at Winlink... "witch, witch, witch...."
Come to think of it... that pesky ECHOLINK is still going on too! Where's my echolink pitch-fork? C'mon, let's get 'em! Bunch of internet-connected morons sucking up my drivel time... LET'S GET ON THE INTERNET AND COMPLAIN, ESPECIALLY IN ALL THE PLACES WE SHOULDN'T BE! Hahahaha.... this is too funny.

[NOTE: If the author wants real results, he should get on Winlink and email his concerns to the Winlink users... that will complete his hypocritical circle and restore balance to the universe.]
Also,
IF THEY CONSIST OF LESS THAN 1%, HOW THE HECK ARE THEY IN YOUR WAY, BUBBA??
All you want is to have your 100%, right? Why can't people just understand that? It's a mad, mad, mad, world...

Researching the author, I see he is a QRP fan.... leaving me to wonder.... WHY would he want to purposefully limit himself to barely enough power to communicate when he has available a perfectly good 50-100w radio market?? That will give him plenty of power to be heard and not too much to drown anyone out.
I'm betting he operates QRP wherever he wishes, forcing others to WAIT while the do-good folks "give in" feeling sorry and letting the little guy have the time/freq.... what a power rush that must be.
Then again, it could be that he's simply experimenting and enjoying the hobby in the fashion he CHOSE by right, etc....
Nah, couldn't be that.

Before anyone jumps on that, be advised that I've already experienced the common orations on the post-nuclear advantages of QRP training. Here's a news-flash boys... after the smoke clears, your QRP station will either be lost in the new and improved noise floor, or be one of the new big-guns on the suddenly quiet bands.... so I still miss the point. But do I make a hole for you when I hear you? Yes, I do. [Refer to that courtesy thing mentioned above.]

Also, if anyone wonders/cares, I have few "friends" on the local repeater too, since I only use it for communicating when a telephone isn't suitable, or whatever the rules suggest.
Curse me for using simplex instead of the repeater most of the time! See, I had this stupid idea, that the repeater is only useful to me when the communication requirements exceed simplex range. I must be a fool.
It seems that contacting my wife on the repeater [preceeded by paging tones to my alert monitor...OMG!!!] then making my contact, passing necessary info and clearing the frequency is just absurd to the local jaw-breakers who inevitably pounce on any break in the silence, almost demanding attention. How rude I am for not sitting in my hot car in a parking lot for an extra 15 minutes every time I need to tell someone something simple and move on.

Don't get me wrong, I love to chat, ragchewing on a repeater [or HF] is no problem to me, but not every time I key a mic for goodness sakes! But, I digress...

I had a bumper sticker one time.... "I love Jesus, it's his groupies I can't stand.", and I wish I could find an analogous "I love radio, it's the operators I can't stand."

So, with my failure to "get it" along with my apparent stupidity, I now relinquish the floor to whomever.

I've got one of those in the junk box. I was thinking of converting
it to solid state using cascaded (J310-311 and 2N2222) transistors,
perhaps a differential set of J310's for the mixer and a single J310
for the oscillator. Not sure about the audio and detector stages yet.
There was an article in an old '73 magazine on converting one of those
sets to solid state and adding a crystal controled converter to receive
40 meters. I've misplaced that issue though.

Converting a "Q5-er" from tubes to FETs would be rather easy.
No real need for the 2N2222s. Would have gobs of space left over
inside an already compact box.

If the 135 KHz IF has an equivalent total Q of 100, the BW would
be about 1.3 KHz, not all that swift for CW and too shart for SSB.

However, the BC-1206 tuning range of 195 to 500 KHz results in
an image at the converter input of 390 to 1000 KHz away from the
desired band. That's worse than the 910 KHz image of an old
455 KHz IF.

The BC-1206 tuning drive wouldn't be fine enough for today's
narrowband style of operating so that would need a fair amount
of mechanical rework. User's choice there.

The linear-in-capacity rotation of the 3-gang variable is good
for an RX Noise Bridge having an expanded parallel-C range...
which is what I used them for. :-)

If I convert it to solid state, I'll probably use it for it's original purpose as an aircraft NDB receiver. Although I don't fly anymore, I have a private pilot's license and still like to listen in. Most NDB's just send their call signs in A2 morse, but some also have live weather reports as well. Only problem is that it only goes up to 400khz and IIRC some of the NDB's in this area are a bit higher in frequency, I could modifiy the tuning range a bit.

This is the idea of a cascade fet-bipolar circuit. The drain of the fet
drives the emitter of the bipolar and the bipolar's base is biased so
that the base sits about half way up the power supply (two resistors).
The fet is self biased with a source resistor for the desired current.
The gain of this circuit is higher than a fet by itself, and the output
impedance will be higher.

The AnArc-5 Q5'ers had 6 tuned circuits in their If but the '1206
only has 3 or 4. So it's BW might be a tad wider. The 1206 also has
no bfo.

> However, the BC-1206 tuning range of 195 to 500 KHz results in

The 1206's dial only goes up to 400khz, but it tunes past that. Maybe
it goes to 420 or 450khz, I don't think it goes as high as 500khz.
(so maybe I don't have to expand the range for my needs).

> The BC-1206 tuning drive wouldn't be fine enough for today's

The vernier drive isn't that bad. I could put an elcheapo 1.5" vernier
dial to drive the tuning knob (if I modify the drive to remove the 180
degree stop). But I think all it really needs is a better bigger knob.

>Greg Ordy did both a kit offering and completed boards about a year ago. Not
>sure if he has more planned or not- it was a labor of love.

Sorting components into kits is *always* a labor of love. I regularly sort packages of about 1000 components into 10 kits of about 100 each, and almost every component has to be individually sorted into trays and repackaged by hand. Every hand movement takes time, and every second is multiplied by some number between 10 and 1000. I dread to think what kind of grunt-labor rate it's actually earning for me.

SMD components are even more difficult and time-consuming to handle, re-package and re-label. Having built an N2PK analyzer, I wouldn't ever consider sorting those parts into kits. It's actually easier to buy the parts yourself, and keep them in the marked bags from Digi-Key or Mouser.

N2PK provides a complete shopping list. For people outside of the USA, there is more information on my 'In Practice' pages.

Don't worry that the minimum order quantities of Rs and Cs are 50 or 100. SMD components are cheaper than wire-ended - and when an 0805 resistor vanishes into hyperspace, you'll be glad you have some extra! (Also ask yourself: how could a kit maker know which parts you're going to lose?)

Above all: if you're really interested, join the Yahoo group.

2983. Lightning and sporadic-E

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-06-27 21:02:28 UTC
From: Johnson <jdwalton@comt.net>
Message-ID: <LNKdnZcSdNcu-l3fRVn-qw@comcast.com>
Source record: 18416

This is the first paragraph of an article in the June 9th issue of Nature, pages 799-801 -- the authors have demonstrated that lightning intensifies the sporadic-E layer. Full article is available at your library.

Lightning-induced intensification of the ionospheric sporadic E layer
C. J. Davis1 and C. G. Johnson1

Top of pageA connection between thunderstorms and the ionosphere has been hypothesized since the mid-1920s1. Several mechanisms have been proposed to explain this connection2, 3, 4, 5, 6, 7, and evidence from modelling8 as well as various types of measurements9, 10, 11, 12, 13, 14 demonstrate that lightning can interact with the lower ionosphere. It has been proposed, on the basis of a few observed events15, that the ionospheric 'sporadic E' layer-transient, localized patches of relatively high electron density in the mid-ionosphere E layer, which significantly affect radio-wave propagation-can be modulated by thunderstorms, but a more formal statistical analysis is still needed. Here we identify a statistically significant intensification and descent in altitude of the mid-latitude sporadic E layer directly above thunderstorms. Because no ionospheric response to low-pressure systems without lightning is detected, we conclude that this localized intensification of the sporadic E layer can be attributed to lightning. We suggest that the co-location of lightning and ionospheric enhancement can be explained by either vertically propagating gravity waves that transfer energy from the site of lightning into the ionosphere, or vertical electrical discharge, or by a combination of these two mechanisms.

The ARC-5 LF version has IF TRANSFORMERS but the insides are
easy to see for detail. The 6 to 9 MHz version IFs (2830 KHz)
had only one tuned circuit in each IF can.

Can't remember what the BC-1206 used in their IF cans, but that
is easy to change inside the present can (it will look just the
same on the outside).

I can't see any advantage of going cascode (JFET-bipolar) when an
insulated gate FET would closely approximate a vacuum tube for

both input impedance (all capacitive) and drain/output impedance
(many hundreds of KOhms). Depends on what is available for the
vacuum-to-solid conversion.

Note: Both input and output impedances will affect the impedance
and Q of the tuned circuits...and the GAINS...for a conversion
with minimum circuit changes. All that has to be taken into
account.

>(so maybe I don't have to expand the range for my needs).

The variable tuning capacitor max:min ratio is roughly 11:1 (no
external parallel capacity). Since the resonant tuning range is
the square root of that, you could have it tune 190 to 570 KHz
with a 9:1 max:min change in resonance capacity. The only real
problem is getting the variable LO tuning to track the front end
since it would tune 325 to 705 KHz (for the high-side) and that
would be a 2.169:1 frequency ratio or 4.706 capacity change ratio.

>> The linear-in-capacity rotation of the 3-gang variable is good
>> for an RX Noise Bridge having an expanded parallel-C range...
>> which is what I used them for. :-)
>>
>True, but the rig is just to cute to canabilze.

Heh heh heh. I agree with you there. It probably is most dense
of any other 1940s era design using 8-pin "medium" size tubes,
including the very compact ARC-5 receivers. Not quite as dense
as the SCR-300 Walkie-Talkie (BC-1000) which stuffed 18 7-pin
"miniature" tubes, a half-dozen coil/transformer cans, and a
five-gang (!) variable capacitor into an approximate 5" x 10"
chassis. [Galvin/Motorola did real good in packaging there]

KEEPING the tubes as-is, with the possible exception of the AF
out (28D7 ?) would yield a straight-AM receiver. ADDING a BFO
via under-chassis bipolar transistor would result in minimum
cannibalization (one extra switch on front panel)...RF and IF
could remain the same. I've forgotten the audio output circuit
of it but recall that AF output power for old aircraft was
rather high (ambient noise in old warbirds was terrible). In a
quiet land environment, the audio output needed is rarely 200
milliWatts into a speaker, much less for headphones. The SCR-300
walkie-talkie (headphones only) had a maximum of 3 mW audio out!

Hint on supply conversion: A 12.6 V "filament" transformer can do the job for all-12 V filaments in parallel. A voltage doubling rectifier (even a tripler if need be) will yield the quite-low B+ for plate and screen. I once did that (long time ago) with a single transformer and voltage tripler for B+, all working into a set of power resistor load boxes, all in a half hour of tack-soldering. Got 30 VDC for B+ at 115 VAC line, less than 5% ripple. Didn't have the BC-1206 then. A critic looking on said "that isn't a good enough test...gotta have the 'real' load on it to 'prove' it." :-) [some folks just aren't convinced until someone else has made a finished production product!]

And this has _WHAT_ to do with homebrew?

2990. Question-Ramsey QRP20c(30c, 40c) and Bands

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-06-28 04:05:06 UTC
From: Scott Anderson <ascension_fl@hotmail.com>
Message-ID: <1119931506.119786.208130@o13g2000cwo.googlegroups.com>
Source record: 18423

I am going to betray my entry-level lack of understanding about the inner workings of radio electronics here, but my question (out of curiosity, more than anything else) is this: Ramsey Electronics offers kits for QRP transmitters for the 20, 30 and 40-meter bands (http://www.ramseyelectronics.com/cgi-bin/commerce.exe?preadd=action&key=QRP-SERIES)... they are dual crystal control (they provide one, and leave space for one more)-- is it the frequency of the crystal *only* determining the operating band in *these particular radios* (and they are being marketed as being for the different bands based on the frequency of the one crystal provided), or is it something relating to the other circuitry itself that (again, with these particular transmitters) that is determining the operating band? I read the .pdf manual on the Ramsey site, but I am still not certain.

Thanks for any insight-
Scott Anderson

Hi Scott,

I don't blame you for being confused--the manuals have no schematic!
But the inductors and capacitors in several places (such as the
oscillator and the low pass filter on the ouput) are different for each
band model, so you would not be able to switch a unit to a different
band just by changing the crystal.

Hope this helps (probably not what you wanted to hear),

Glenn Dixon, AC7ZN

In general when you build a transmitter you need filters designed for
the frequency band -- if no where else, then there should be a final
filter that prevents harmonics getting out.

Yes, with "Winlink over Pactor III" being a very noticeable offender here, in that it happens to be so popular at the moment.

> It seems as if it would be very difficult to make these
> automated stations be friendly to other users.

SCAMP intends to address this, and it is a very important problem to be "fixed." There are many people who dislike the idea of using any amateur radio bands for linking Internet data/e-mail/etc. at all (my hypothesis is that they must not have been all that thrilled with packetmail either, but the Internet is the straw that's breaking their backs), but of those who aren't 100% opposed to the idea to begin with, Winlink not presently using busy detectors is a legitimate complaint.

> Both the pro and con in this argument are absolutely unwilling to listen
> to/believe the other side.

There's a lot of this going on, to be sure, but the fact that SCAMP is making slow and steady progress suggests that there are some level heads that will (hopefully) prevail.

If you read the manual, I believe they have one manual for all models, you insert different components based on which band you are building. The various bands require different components in the amplifier matching, output filter, etc circuits.

Tom - AC9TS

2995. Amateur Newbie Questions: Homebrew RF Test Equipment?

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-06-28 18:13:31 UTC
From: Timothy@tholtom.freeserve.co.uk

Source record: 18428

Amateur Newbie Questions

Question 1)

I studied Electrical Engineering (20 years ago
now...lots of theory and little practice...) I
remember we had access to very expensive RF test gear,
amongst which was a Hewlett-Packard RF Spectrum
Analyzer (US$200,000 (!!!) I seem to remember). A
very, very nice piece of equipment. At that time the
IT revolution/DSP was still very much gathering steam.
Now that PCs with 3.4 GHz processors are available,
plus pretty sophisticated DSP development systems, at
a reasonable cost (several hundreds of dollars), is
there a good homebrew RF spectrum analyzer
available... I've seen plenty of AF spectrum
analyzers available (Spectran etc.) ... What I'm
after is something like:

low cost development board +
high end PC +
GNURadio (or whatever) +
Extensions to GNURadio

= Pretty (or very) good RF spectrum analyzer

Question 2)

In a similar vein, though of course not as expensive,
Does anyone have circuit diagrams for a homebrewed
function generator, working against an accurate
internal reference, and putting out: pure sinusoids,
square waves, saw tooth functions, white noise ....
etc.

low cost development board (DAC??/Digitally Controlled
Oscillator) + Buffering and Amplification +
PC +
Homebrewed Software

= Pretty (or very) good software controlled, test lab,
function generator...

Anybody got any ideas...sorry if the answers to these
questions are blindingly obvious!!!

Thanks

Tim

Its a lot easier (unless you are just into building your own) to buy all
that old time expensive gear for peanuts on eBay! Usually goes for pennies
a pound these days. Still far better than anything you could hope to
build..Why reinvent the wheel?

There are a couple out there. One with some of the best specs is the one designed by Tom McDermott that TAPR will offer as a kit and that TenTec will be manufacturing. More info: http://www.tapr.org/kits_vna.html?PHPSESSID=af26a6881baf8f52743f3c5d1a637bfc . The price was something in the ballpark of $600, which is nothing compared to a new HP, Rohde & Schwarz, etc. network analyzer (many such analyzers are still WELL above $20k...). If you can add another "0" to your price tag, though, items on eBay do start to look attractive. :-)

One of the design limitations of Tom's analyzer is that the upper end is 100MHz; another is that the dynamic range is something like 60dB.

> low cost development board +
> high end PC +

> Extensions to GNURadio
> -------------------------------
> = Pretty (or very) good RF spectrum analyzer

Well, not to put too much of a damper on your hopes here, but I'd have a couple of concerns: (1) the GNURadio USRP board isn't particularly designed for "really weak signal" work. Last time I asked (back at Dayton), they hadn't even measured how much noise was running around the board, but I'd be really surprised if it's anywhere near as quiet as a good spectrum analyzer. Secondarily, although there is already a lot of software out there for GNURadio and Tom's network analyzer board, it's nowhere near as "polished" as commercial offerings.

I think the USRP board is one of the best new things to come along in amateur radio in a long time -- it's opening up a wealth of opportunities for experimenting that would have been much more expensive to get into previously. Also, GNURadio is (at least in theory) not too tightly tied to the USRP (they started with some PCI ADC boards, after all), so designing a really quiet vector or scalar analyzer to plug into its "architecture" would be a pretty cool undertaking.

> Question 2)

> etc.

This actually is a pretty good application for a USRP, at least if you don't need super tight control over stuff like phase noise. It's very easy to get the thing to output any arbitrary waveform you like.

It has something to do with transmitting and receiving...and for those of us
who have hb'd our own receivers it makes a little sense out of the natural
world.

Sorry, Hank,

I thought maybe you might be one of the current generation of young-uns who don't seem to be able to understand the meaning of the contracted "do not" or "can not", and I tried to poke a little fun in your direction. I know it's not cool to criticize the statement "I could care less" when the intended meaning is "couldn't care less", but sometimes I just can't control myself.

My newsreader used to miss posts all the time - - many threads started with '"re-", but it's getting better. At least your new post didn't meet up with dead silence.

No worries, as the Aussies say. I finally got it going. I was blocking spam and fatfingered the keyboard and blocked myself. But when I unblocked me, it still didn't work and I rebooted both the PC and dsl modem and now it works.
As far as: "I could care less" when the intended meaning is "couldn't care less", both are correct and mean the same thing according to an article I read that was in the local paper. I don't agree but who am I, and who gives a shit about my opinon, no one!
The English language is not what it used to be, pretty well defined in the classroom. Today, useage by the masses can and does change meanings of terms. You gots to roll with dem punches if you don't wan ur ass kicked'

You just can't get too picky with a language in which "fat chance" and
"slim chance" mean the same thing.

Decoding MSK as FSK will give you way less than optimum bit error rate vs. noise. Unless the MSK is coming in on an FM channel you should consider decoding it as PSK.

DsPIC + code -- that's a single-chip solution, and in current production!

I've been looking for information on varactor-tuned front end/preselectors and really have not found much in the way of practical/DIY implementations.

I've seen the commercial offerings from (e.g.) www.polezero.com and vague references to others.

Can any of you here recommend a text/app notes/practical circuits that can be studied and/or emulated? I'm interested in VHF applications that could be uP controlled (via D/A, etc.)

Thanks,

Bill

It would seem to be a 152.815 TRANSMIT xtal...the fundamental freq of course would be something different. The third wire could be a ground for the case of the xtal.

A mi me parece un cristal de 152.815 Mcs de salida para un transmisor. La frecuencia basica serï¿½ algo diferente, depende en el modelo del equipo, su frec. IF, etc. El alambre tercero serï¿½a una conecxion aterrizada del casco del cristal. 8-76 mas probable significa la fecha de fabricacion.

I think part of the reason for little information or enthusiam is the diodes tendancy for IMD on strong signals. This increases the complexity of the circuit. You might check with the ARRL and see if any information is available from past QEX articles. I am researching the same thing for a HF preselector. I am going to experiment with solid state relays. Just a suggestion. Try the Vishay site as(http://www.vishay.com/solid-state-relays/). I have found little info on varactor tuned pre-selectors

These option-WJ models aren't very common; this is the first one I've seen. It tunes from 5 kHz-8 GHz in two bands which are both wider than normal 492/492A analyzers cover; you can see the spectrum from near DC to 4.2 GHz in a single sweep.

If you don't need full coverage to 21 GHz, this 492A may be a good alternative to the more-expensive entries in the 490 lineup!

And what magic resistive combiner makes VGA into NTSC??? There is
no such thing. There are active models which do this, but if your
VGA output is 640X480 or more, then NTSC will make the video suck.
NTSC does not have the bandwidth. Yes you can take a properly modulated
channel 3 signal, run it into a balanced mixer (well almost any mixer)
and add your favorite local oscillator signal and get 2 signals in
the uhf band. LO + ch3 and LO - ch3.

Good luck. Here's looking at ya or at least the unviewable signal.

Better bait, and a more powerful trolling motor.
